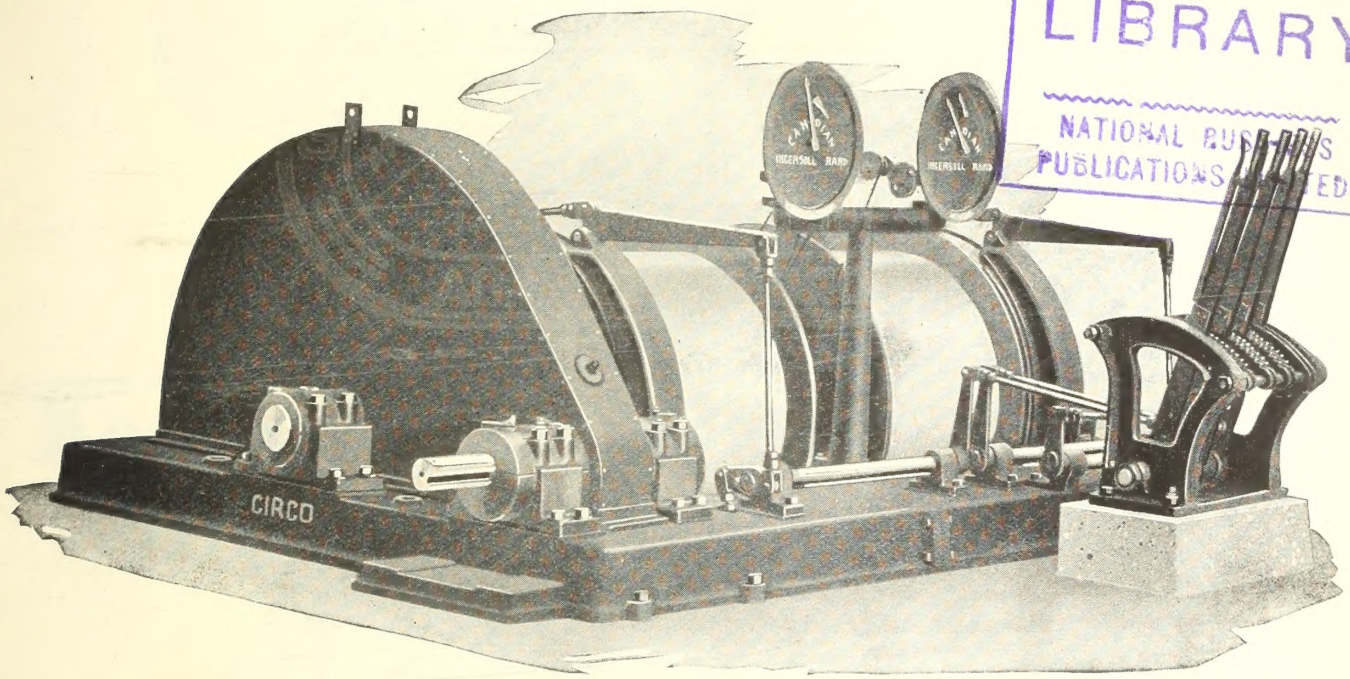
"CIRCO" HOISTS

Return to LIBRARY
NATIONAL BUSINESS PUBLICATIONS LIMITED



YOUR HOIST EARNS EVERY DOLLAR IN YOUR TREASURY

The earnings of your hoist depend on the tonnage it can handle and the tonnage it can handle depends on its power, reliability, and ease of control.

To design and build hoists capable of hoisting or hauling heavy loads continuously at high speeds to meet the requirements of modern mines and collieries calls for wide experience, engineering skill, and exceptional manufacturing facilities.

The size and type of hoist; how to equip it for best results and similar questions are most satisfactorily met by close co-operation on the part of the mine management and the hoist builder.

To the solution of such problems "Ingersoll-Rand" engineers bring the knowledge and experience acquired through more than half a century's association with the mining industry, plus the backing of an excellent manufacturing plant and a highly trained force of skilled mechanics, many of whom have been with the Company for twenty-five years or more.

No matter what the service, size, type of drive or equipment required, you can obtain a "CIRCO" Hoist to suit.

Consult our nearest branch.

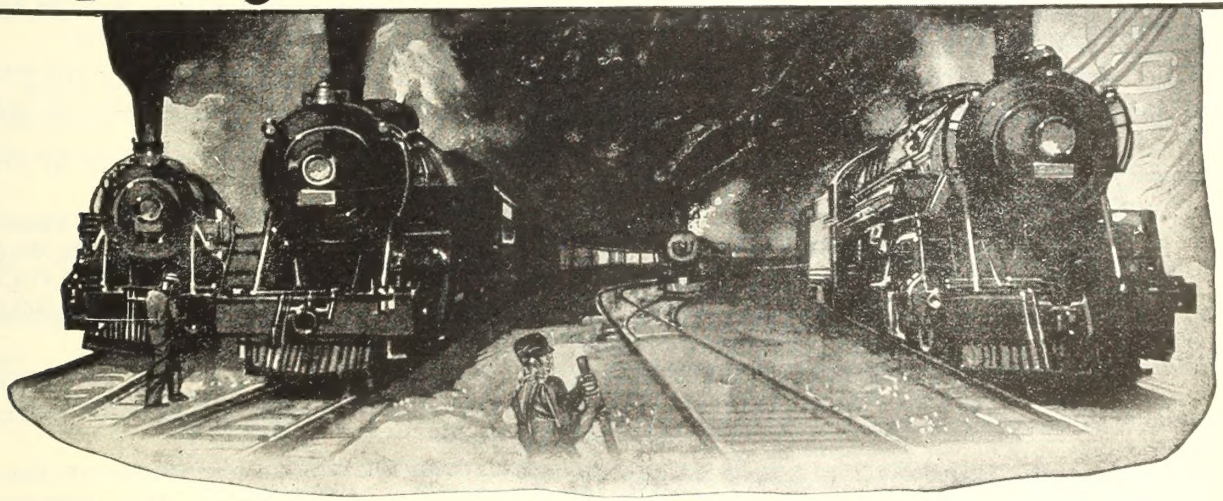
Keeping the Wheels Turning



IDLE engines, idle ships and broken machines cause waste and loss. Dominion Service contributes largely to the repair work which keeps the wheels of mighty locomotives, marine engines and industrial machinery turning.

Dominion Service places an unlimited supply of pure oxygen and dissolved acetylene in safe, easily-handled cylinders, when and where it is needed for welding and cutting work. No matter where your plant or construction job is located, we can ship by the shortest route from any one of our ten plants and warehouses all the oxygen and dissolved acetylene you require, on telegraph notice.

This is our idea of service—let us tell you more about it. Our proposition will mean profit for you. A representative will call at your request.

Ontario's Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

Hon. H. MILLS, Minister of Mines

Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines

Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth $48,128,387,of which the metallic production was $27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

Year.	Value.	Year.	Value.
1891	$4,705,672	1906	$22,388,383
1896	5,235,003	1911	41,976,797
1901	11,831,086	1916	65,303,822

Dividends.

Dividends and bonuses paid to the end of 1921 amounted to $23,140,734 for gold mining companies, and $84,388,185 for silver mining companies or a total of $107,528,919.

Mining Regulations.

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

CANADA'S MINERALS AT THE BRITISH EMPIRE EXHIBITION

Canada's mineral industry will be represented at the British Empire Exhibition in London next year by an exhibit that will surpass in excellence anything heretofore attained. Our Dominion government was slow to ratify the final arrangements for Canada's share in the Exhibition; but since the official announcement was made, practical measures have been formulated and put into effect with such thoroughness and despatch as to ensure a Canadian exhibit of which we shall be proud.

The Canadian exhibits are to be housed in a building 400 feet by 200 feet, one-half of which is alloted to industrial exhibits and the other half to natural resources. The mineral exhibit has been assigned one wing of the latter section, a space 80 feet by 110 feet, with an additional space in the adjoining broad aisle. The building is to be of temporary construction, and work on it has been commenced under the direction of Mr. A. W. Tolmie, Canadian Government Exhibition Commissioner, who left for London with a staff some weeks ago to initiate the work. The building was designed in Canada and is being built by the Dominion Government. A large part of the material, as for instance the marble used for decorative purposes, will be sent from Canada.

The mineral exhibit is designed to represent Canada's mining industry from coast to coast. The general arrangement of the exhibits will be geographical, so that the visitor can commence at one end with the mines and quarries of Yukon and British Columbia and, as he walks, view in succession the mineral wealth of the prairie provinces, Ontario, Quebec and the Maritime provinces. Within these geographical divisions the arrangement is, however, directed by the natural association of the minerals; silver-lead-zinc, gold-copper, natural salts, nickel-copper, silver-cobalt, asbestos and chrome, and coal exhibits, for instance will each be grouped. Within these groups the individual specimens or groups of specimens from specific mines or mining camps will be labelled to show their point of origin and will be adequately described.

As it is not possible to provide as an integral part of these exhibits all the information about Canada's mineral industry it is desirable to convey to visitors, a special book is to be prepared by the officers of the federal Department of Mines. It will contain appropriate descriptions of Canadian geology and of our mineral deposits and will include a special map.

The proprietors or managers of mines and quarries throughout the Dominion have been invited by the Mineral Division of the Canadian Government Exhibition Commission to send exhibition specimens of their ores and minerals to the headquarters in Ottawa. Specimens from 50 to 250 pounds in weight are requested, though case samples 6 by 8 inches are acceptable also. These specimens may be from producing mines or from prospects. The Commission asks the coöperation of all those in a position to provide these specimens, that the collection may be as fully representative and as interesting as possible. Freight charges will be met by the Commission.

The cases that will enclose the larger part of these exhibits are ranged along the three walls of the space allotted, a total of 270 feet. They are twelve feet in height, and are surmounted by Canadian wall marble, above which, in the cornice, are illuminated mining scenes, 10 feet by 3½ feet, printed photographically on translucent linen and coloured by hand. In the centre there will be floor cases. A special ceramic exhibit, now being prepared by the Ceramic Division of the Mines Branch, will occupy 40 feet of wall space in the adjoining aisle.

The officer of the Exhibition Commission in direct charge of the mineral exhibit is Mr. W. D. Dalgleish, who has acted in a similar capacity at all Dominion Government mineral exhibits for the last twenty years. It is as a result of this long experience that it has decided the exhibit shall represent Canada as a whole, though there will be a provincial division in the arrangement as outlined above. A few weeks ago Mr. Dalgleish visited the provincial mining authorities from Victoria to Toronto, arranging for the complete coöperation of each, and now is engaged in a similar tour of the remaining eastern provinces. By this means he has engaged the aid of those most competent to make the Canadian mineral exhibit at the Exhibition an outstanding success.

CARBONISING PLANT FOR CANADA

While scores of fuel specialists throughout the world are busily engaged searching for a solution of the domestic fuel problem by way of the low-temperature carbonising of non-coking coal, and while hundreds more are just as busily engaged in argument as to the merits of processes proposed or under investigation, a practical business man has decided to put one such process to the test. Mr. Henry Ford is reported to have under construction at Walkerville, Ontario, a

carbonising plant designed by Messrs. Emil Piroy and Ralph D. Lamie. The problem is one of vast importance — even more important than the coking of coal for domestic use, as most bituminous coal is non-coking, and the yield of by-products is greater by the low-temperature process.

The numerous serious attempts to solve the carbonisation problem, both in Canada and elsewhere, are fully warranted by its importance. Its solution would be not merely of national but of world-wide importance. Particularly is it of importance to us in this country, with our deficiency of high-grade fuel as well as of motor fuel. If, by reason of the genius of these two inventors and the business acumen of Mr. Ford, the problem should be solved on Canadian soil, it will help notably to swell the meagre total of our present industrial research and may even stimulate the concerted and consistent work of investigation in many branches of industry which alone can ensure a full reward to Canadian workers and investors.

NO SIGN OF GRACE

The science that deals with human life will always take precedence over its sister sciences. It appeals to every mortal man, and to most of us in a very personal way. Death and disease are facts that obtrude themselves upon even the most obtuse. Research in medicine has, therefore, an appeal to the popular imagination that is enjoyed by no other line of investigation.

We join heartily in the congratulations being accorded our legislators in Ottawa on account of their well-judged action in the case of Dr. Banting. His successful search for a cure for diabetes warrants the most generous reward the nation can bestow upon him, and the annuity of $7,500 voted by the Commons is merely a fitting token of our appreciation. Titular honours are no longer accredited in Canada, else Dr. Banting would enjoy the privilege of knighthood as well.

We cannot join fully, however, in the chorus of approval, for part of it is undiscriminating. Our present parliament is not at all notable for discrimination, nor yet for positive action. The annuity to Dr. Banting is, we take it, a lucky stroke, impelled by a fortunate accident of circumstance rather than by a stated policy. In few other instances has our principal governing body shown discrimination in spending the national funds it holds in trust. It costs our legislators nothing to make this most appropriate acknowledgment of our debt to Dr. Banting; *we* foot the bill. Many times the amount of this annuity is pocketed, without proper legal warrant, by members of parliament who have raised their own sessional indemnities by an extra thousand dollars.

No—we can discern no sign of grace in Parliament's recognition of our distinguished young Canadian doctor. When they shall have followed this with the establishment of a national institute for research, and shall have saved the annual cost of this and many other such paying investments by means of the honest and economical administration of our national income, then we shall be ready to say, "Parliament is reformed! Parliament has developed a conscience and good judgment! Long live Parliament!"

MR. DRESSER'S LETTER

Today we re-print a letter from Mr. John A. Dresser to the *Financial Times*. It discusses a question that receives but meagre attention from either mining engineers or the financial public; yet it is a question that warrants the best attention the Canadian mining fraternity can give it, and is of first-rate importance to the general public.

On numerous occasions we have pointed in these pages to the fact that mining investment is as yet almost totally unorganized. Vast sums of money pass each year in the name of mining that never reach mine or mill. A large part of this is available for honest and discriminating mining investment if we, the mining men of Canada, will take the pains to go and fetch it It is good money, else the promoters of dishonest "mining" ventures and the purveyors of bogus stocks would not be so anxious to get hold of it.

Mr. Dresser ends his letter with a question. He asks whether the people that are fleeced at present by means of illicit and injudicious issues of mining stock are capable of protection. We would reply that, were an alternative to the present dubious or worthless issues of stock available, a substantial fraction of the present investors would choose it. The main benefit to the mining industry would not come, however, from these. It would come from the many investors who have now the impulse to put their money in mining ventures, but who can find at present no accredited agent to whom they can entrust their funds. It is principally for this reason that we urge the establishment of a mining brokerage house to which both prospectors and investors can turn with the implicit confidence that they will get a "square deal."

We hope that Mr. Dresser's lead will be followed by other mining men that have the welfare of their industry at heart. The public discussion of mining investment presents an opportunity for public service.

THE QUEBEC REPORT

The 1922 report of the Quebec Bureau of Mines is unusually full of interest. Mr. Denis' warning under the caption "Mining Ventures and the Public" follows up his own policy of years past, and exemplifies as well the expressed attitude of Premier Taschereau and his colleagues. Mr. Taschereau has promised recently that he will follow up his interest in this mat-

ter by introducing legislation designed to curtail the operations of the stock-selling rogues that now infest the province. Quebec is now almost unique in having no statutes whose express intention it is thus to protect the public. We hope that the Bureau of Mines report for 1923 will record the passage of an adequate and judicious "blue sky" law.

Two outstanding features of the report are the included reports by H. C. Cooke on the Opasatika map area, and by F. J. Alcock on the Gaspé zinc-lead deposits. The report on the new gold area is particularly interesting, as it has not yet been published in its original form. Both reports are by officers of the Geological Survey, and are printed in the Quebec report with the Director's permission. This, of itself, is a most excellent and useful arrangement; but it draws attention to a state of affairs in Quebec that we hope will receive speedy attention.

The Bureau of Mines is now, and always has been, the orphan of the executive community of Quebec. It receives little consideration and less financial support from the provincial government. This is in spite of the fact that the mineral industry is bound to become the principal industry of the province, whose arable land constitutes a smaller proportion of its area than any other province. Fortunately this fact is beginning to penetrate to the consciousness of the political executives. When they become more fully conscious of the position of prime importance the mineral industry must assume in their province, we can expect rapid and effective action. For years past Mr. Denis, struggling to cope with the situation, at first single-handed and now with a totally inadequate staff, has said that a gold mining boom in Quebec would effect a metamorphosis in the attitude of Quebec legislators. The boom has come, and the fulfilment of his prediction will follow.

THE ASBESTOS MILLS

Today we print the first article of a series by Mr. Ernest Booker on the Quebec asbestos field. Mr. Booker dwells on the recorded fact that a large part of the asbestos in the rock as quarried is lost in the process of milling. In a subsequent article he will show how, by comparatively simple means, most of this waste can be avoided.

In the 1922 report of the Quebec Bureau of Mines, the present wasteful milling method is referred to in no uncertain terms. The mill in Thetford of the Asbestos Corporation is referred to thus: "A new dust set-
" tling chamber has been erected on the west side of
" the mill. By this means, it is said, over 80 per cent.
" of the dust which formerly escaped outside and
" polluted the air, is now collected, bagged and sold.
" Some five tons per 24 hours is thus collected." This refers to the mill that was burned recently. The mill now under construction will, no doubt, include the improvement added to the old one.

The mining and milling practice of the Quebec asbestos field has remained strangely impervious to many of the influences that make for progress. During recent years some obvious waste of time, material and energy has been curtailed; but much remains to be done along this line. In former years this waste merely reduced the scale of profits, since the field enjoyed virtually a monopoly of the world's markets, and prices were almost what the operators chose to charge. This is far from the case today, particularly with the longer grades of fibre, as is evidenced by the fact that crude No. 1 dropped in value from $1,281. in 1921 to $648, in 1922, and crude No. 2 from $446. to $265. Some competent students of the asbestos market predict that the prices of long fibre will drop still more, which will remove our asbestos pits still further from the bonanzas of former days.

The plain fact is that, if Quebec is to hold even a fair share of the world's asbestos markets, the pits and mills must be operated with the utmost economy. Otherwise, and quite unnecessarily, the province will lose the larger part of its principal mineral industry, as well as a substantial revenue, and the prosperous communities round about the quarries will gradually assume the gloomy and disheartening appearance of the deserted mining town.

Last week the bill authorizing the bounty on copper rods and bars contained in Mr. Fielding's budget passed the Commons. There was some opposition to it, mainly from Western members, who wanted to see proof that the bounty is really required. Happily, this opposition was overcome by a substantial majority, and the copper industry will receive the reasonable measure of aid required to establish it soundly.

CANADA

Anniversary

In humbleness, O, Lord, we ask
That Thou should'st fit us for the task,
  The duty, and the privilege, of giving
Our best to work we have in hand;
That of ourselves we may demand
  The constant effort after worthy living.

Let not our pride of country, race,
Or power, for one brief day efface
  Remembrance of the debt we owe the past;
Let not self-interest or greed,
But service, be our living creed,—
  Lord, may we cherish good and hold it fast.

May we our heritage transmit
To children who are strong and fit
  To treasure it far better than have we;
O, help us play the part of men,
That, when we pass, our children then
  May love and honour Canada and Thee.

ANON.

The Nation's Birthday

By A. R. R. JONES, Editor, Journal of Commerce

On Monday of this week we celebrated Dominion Day with grateful hearts. And, indeed, in this favored land — a nation in itself and yet one of the galaxy of nations that surrounds the British Throne — we have much reason for gratitude.

Our natural resources are of vast extent and varied and manifold in character. First in importance is the soil devoted to agriculture. In Eastern Canada mixed farming, dairying and fruit growing are firmly established industries, but not more than half of the estimated area of 110,000,000 acres fit for agriculture in Eastern Canada is at present used for that purpose. The excellent railway service enjoyed by this part of the Dominion, the rapid improvements that are being made to the highways there, and the fine location of its ports all render easy the cheap and rapid transportation of agricultural products for delivery to home and foreign markets. In Western Canada, although the agricultural industry, as we are constantly reminded by those engaged in it, is not without its own pressing problems, yet the three Provinces of Alberta, Manitoba and Saskatchewan have been dowered with agricultural resources sufficient to support at least five times their present population. In fact, in these three Prairie Provinces, only about 18 per cent. of the total area of land with cultivation possibilities has, thus far, been put under crop.

Next in importance to the products of the farm are the products of the forests. This country possesses the enormous area of 1,800,000 square miles of forests. This, however, when considered from the standpoint of commercial material is reduced by one half, since there are extensive areas in the subarctic and subalpine regions that do not support trees of sufficient size or in sufficient quantity to make their utilization profitable, even for pulpwood. Thus the forest area, from the viewpoint of commercial material, must be considered as reduced to 900,000 square miles. And, during the past seventy-five years, at least one half of this commercial forest area has been burned, and most of it not once only, but several times. Thus we have today about 450,000 square miles of forest yielding commercial timber, that is to say, sawlogs and pulpwood. Dean Howe, of the Faculty of Forestry, Toronto University, estimates the total forest resources of Canada at 553,750 million feet board measure of saw material, and 1,297 million cords of pulpwood. These resources, even though reduced as above, constitute a magnificent heritage, and it is satisfactory to know that Canada is recognizing that in her forests there is a great source of wealth needing conservation and development to the utmost.

In the great nickel, copper, silver and gold deposits of Ontario; the copper, gold, lead and zinc deposits of British Columbia; the asbestos and gold deposits of Quebec; in the mineral potentialities of the great hinterland of Northern Canada; in the gold and copper ore bodies of importance which are being developed in Northern Manitoba; in the coal deposits of Nova Scotia, Saskatchewan, Alberta and British Columbia; Canada possesses vast mineral wealth which is bound to play an increasingly important part in the country's growth and prosperity.

Few countries possess waters that afford such scope for gigantic commercial fishing enterprises as do those of Canada. This country, unlike so many other lands, is not hemmed in by the territories of other peoples, but is, on three sides, bounded by the salt sea water, while inland it is traversed by many streams and rivers which take their rise in thousands of lakes, among which are some of the greatest bodies of fresh water in the world, practically all of them abounding in fish. Both the deep-sea and inshore fishing grounds are of vast extent. Among deep sea fishing grounds must be mentioned the famous "Grand Banks" of the North Atlantic from Labrador to the Gulf of Maine; the Gulf of St. Lawrence; the Bay of Fundy; and the Pacific fishing grounds estimated at from 100,000 to 150,000 square miles in extent. The inland fishing grounds include the Canadian portion of the Great Lakes and the countless rivers and lakes occurring from east to west and north to the Arctic seaboard, the total approximating to some 200,000 square miles in extent.

Another source of natural wealth with which Canada has been phenomenally blessed is her water-powers. There are installed to date throughout the Dominion water-wheels and turbines to the extent of 2,909,659 horse-power. However, it would not be correct to place this figure in direct comparison with the minimum or maximum available power figures and therefrom deduce the percentage of the available water-power resources developed to date. An allowance must be made for the average ratio between water-wheels installed and the power available. An analysis of the water-power plants scattered from coast to coast, concerning which complete information is available as to turbine installation and satisfactory information as to stream flow, gives an average machine installation of 30 per cent. greater than the six-month flow maximum power. Applying this, the figures quoted above therefore indicate that the

at present recorded water-power resources of the Dominion will permit of a turbine installation of 41,700,000 horse-power. In other words, the present turbine installation represents only 7 **per cent** of the present recorded water-power resources. The 2,909,659 horse-power at present installed throughout the Dominion is apportioned to the following uses: (1) 2,144,870 horse-power in central electric station for general distribution purposes, such as operation of street railways, operation of mines, operation of electro-chemical and electro-metallurgical industries, operation of pulp and paper mills and for general industrial, municipal and domestic use. (2) 484,228 horse-power installed in pulp and paper mills. In addition there is used in the pulp and paper industry 160,577 horse-power purchased from the central electric station installation: and (3) 280,561 horse-power installed in industries other than central electric stations and pulp and paper mills.

Such, in barest outline, are some of the natural resources in the possession of which we are so signally fortunate. This possession it is which must (humanly speaking) inevitably determine that, provided the resources in question are understood aright and used properly and economically (in the best sense of the word) Canada will occupy an increasingly important place among the nations of the earth — at any rate, on the material side. We are fortunate, further, in the fact that our opportunities, insofar as the upbuilding of a great country is concerned, are still nearly all in front of us. We have much to learn — and we must learn much — from other and older lands and notably from one land, the most majestic, as she is the most motherly. We can learn from them in the realm of art, of literature and of science, and especially as regards the last-named, in the matter of the application of scientific education to the advancement of agriculture and nearly every other industry. Moreover, we are able to learn much, not only from their accomplishments, but also from their mistakes. Some blunders Canada has made in the work of nation-building — but they have been, for the most part, blunders incidental to, if not inseparable from, a pioneer condition. But as yet they are none of them irretrievable blunders. In one respect, at least, we are, as yet, happy. In our cities, so far, slum conditions as they are known in London or New York or Liverpool or Chicago, have not established themselves — conditions which are the certain breeding-grounds of unemployment, want and vice. In Canada, we have the opportunity to build up a State in which the whole body of citizens will be able to lead clean and decent lives, shorn of none of the necessaries of life and permitting of time and space for appropriate recreation and spiritual and mental improvement. None of the economic evils that afflict older countries has, as yet, got a stranglehold on Canada. Let us see to it that none of them does.

On this, the Dominion's birthday anniversary, it is inescapable that Canadians generally should be in reflective mood. As we have said, our national heritage is one of magnificent extent, and vast and varied resources. But material wealth and resources do not make a nation. It is five years now since the termination of the war in which the young manhood of Canada conferred an undying lustre on her name. How have we met the test of the years of peace since then? Better than some other countries, no doubt. But they will be superficial judges, indeed, who will say that, as a people, we have met those years in a spirit worthy of the devotion of those lads who gladly gave their lives for a noble cause. We have somehow largely missed the inspiration to unselfish service that we ought to have derived from the blood-stained fields of France and Flanders.

Do we not still, the majority of us, place a false estimate — and one as unsatisfactory as it is false— on the tawdry glories of wealth and on the pleasures that wealth can bring? Are the big interests, on the one side, and organized Labor, on the other, less selfish and self-seeking than of yore? Do our Governments display any more predisposition than of old to initiate constructive legislation for the benefit of the whole people? Have we made any solid and substantial progress in the formation of an honest public opinion? Are we more ready, individually and collectively, to give willing and useful service for the common weal, to subordinate private or sectional interests to the common good? Are we less prone to measure individual merit and national progress alike mainly in terms of dollars? In a word, are our civic ideals loftier, our personal ambitions less ignoble?

Let us ask ourselves such questions as these — and answer them honestly. In that case, there is little doubt that we shall realize that, in spite of the manifold blessings that Providence has granted us, there yet remains much to be done ere we can worthily tread the path of true national greatness or worthily fill the place Nature seems to have assigned to this favored and fortunate land.

GARNET AS A PRECIOUS STONE

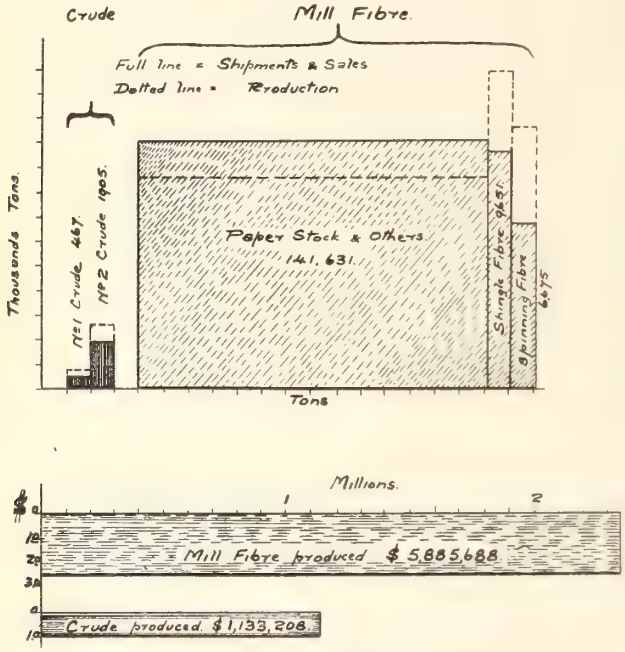
Garnet crystals are sometimes perfect and often enough to be of value as gems. Most of the varieties of garnet are used as gems when transparent crystals are found. Jewellers use red and yellowish brown garnets under the name "hyacinth." Garnet crystals can be recognized by their roundish shape and their hardness. Good crystals may be found in schists, particularly mica schist and chlorite schist, in slate, in crystalline limestone and serpentine near contacts with igneous rocks, in pegmatite granite, and in gneiss. Beautiful crystals are found in mica schist along the Stickeen River, B. C. Green chrome garnet of gem quality has been found in Oxford, Ontario. Very fine gem garnets have sold for as much as $50.00 each. Good crystals of one carat weight have been valued at from $1.00 to $5.00 each. (One carat is about 3 1/3 grains)

The Quebec Asbestos Industry

1. — Losses in the Milling of Asbestos

By ERNEST BOOKER

In the past, the asbestos industry in the Province of Quebec has been largely a crude fibre business, with the mill grades of fibre as a secondary consideration. While crude fibre has been unquestionably the most profitable, to a large extent this business has now gone elsewhere, due to the discovery and development of new ore-bodies in different parts of the world. The importance of the



Comparison of Production & Demand for Canadian Crude, & Mill Fibre 1922.
based on Mines Report 1922. Province of Quebec

Fig. 1.

business in mill grades of asbestos fibre is therefore obvious. Fig. 1. graphically shows the comparison of the two during the past year. In 1921 the business done, while small, was much of the same order.

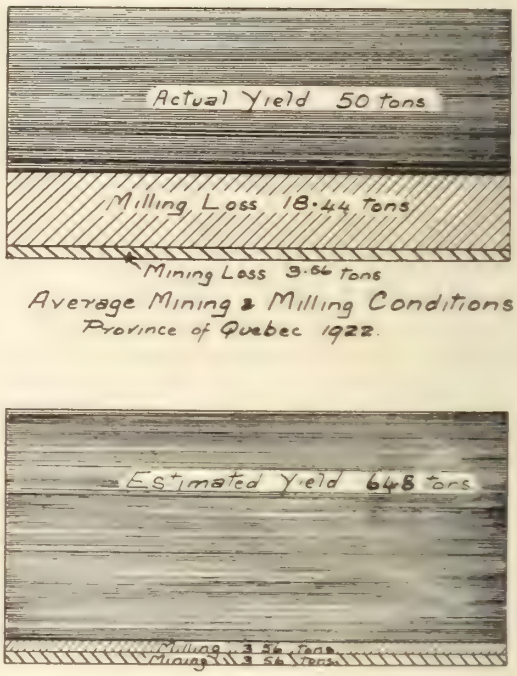
Future Profits are in Mill Fibre

It will be noticed in Fig. 1. that while the production of crude fibre exceeded the sales and shipments, the opposite occurred in the mill fibre business with the exception of two grades; the production of asbestos paper fibre being considerably below the sales. It is therefore to the mills that we must look for the most profitable business in the future.

Possibly there are some who, while knowing their mills are not efficient, do not realize what the inefficiency means in actual loss of fibre production or yield, and its value in dollars and cents. Where a mill is not doing all it can be made to do, things must change, and change rapidly, or this mill fibre business will also go elsewhere.

30 per cent of Fibre Now Lost

At the present time there are many losses in the mills in operation, and of course while it is hardly possible to mill and get 100% efficiency or fibre extraction, yet the actual milling efficiency can be greatly increased. From information gathered recently, it appears that the average efficiency of the mills in the Province of Quebec is about 70% and in some cases is as low as 50%. To illustrate this appalling state of affairs, Fig. 2. shows approximately the loss of fibre taking place daily, for every thousand tons of rock milled. Note that this is something over 18 tons, whereas the actual fibre loss in the mining of the ore is about one-fifth of this quantity. One cannot avoid fibre losses in the mine, especially if it is of the



Average Mining & Milling Conditions
Province of Quebec 1922.

Efficient Milling Conditions

Estimated Loss of Asbestos Fibre per 1000 Tons of Rock.

Fig. 2.

open-cut type; but in the mill, losses can be largely eliminated, and must be if the Quebec asbestos industry is to prosper.

From the same chart, Fig. 2, you will notice that with efficient milling conditions the mill losses are estimated at about 3 1-2 tons per thousand tons of rock milled.

Losses are in Dumps and Dust

To find where the losses actually occur in the process of milling must be the first step in considering an improvement. About half the mill loss can be put down to inefficient separation of the rock and fibre in the mill, which results in a considerable quantity of fibre going to the tailings dump with the rock. The other half of the fibre lost in the mill is not in any one place, but is scattered about the surrounding countryside with the dust that pours from every window, door and crack in the mill building. Now, it is quite a problem to collect asbestos fibre from the surface of the land, but it is a simple matter to prevent the leakage of this dust and fibre at its source in the mill.

In many cases it is no individual machine or type of machine that is at fault, but the arrangement of the mill as a whole. In any case the losses can be reduced and much more profitable operation result.

Increased Profit Possible

Having pointed out the importance of the mill grades of fibre from a business standpoint, and the losses that are now occurring in the production of these products in tons of fibre per day, it is only reasonable to give a little attention to the value of the losses and what the increased recovery would mean in revenue. Fig. 3. shows graphically just what may be expected in the production of mill fibre and its value, compared with the actual production and revenue for 1922. Both diagrams are based on the same tonnage of mill rock.

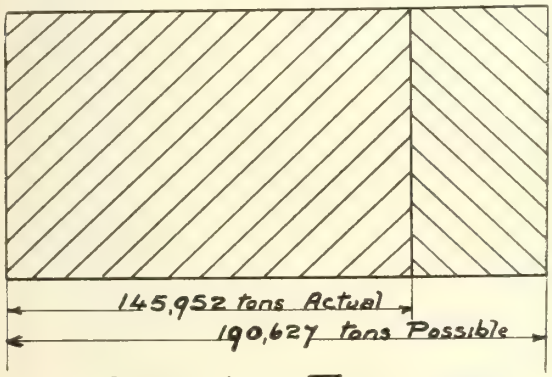


Fig. 3.

The increased revenue from the increased fibre production does not, however, equal what the mine and mill owners actually lose by the operation of an inefficient mill, or possibly an efficient mill operated uneconomically. In addition to the actual revenue from the increased fibre produced, the cost of 25% of the mill rock at the mill must be accounted for, since one is separating virtually no fibre from this quantity of ore when using an inefficient mill. This cost, amounting as it does to quite a respectable sum daily, is lost daily, is lost sight of, or rather one should say is included in the mining and milling cost of the other 75% of ore. The unit costs of mining and milling thereby become inaccurate and the actual unit costs are unobtainable. This discrepancy, while passing unnoticed, reflects no credit on the management and in many cases seriously handicaps both the mine and mill managers, to say nothing of the owners themselves.

Wasteful or inefficient milling of any mineral can find no justification in Canada, and appears to be either downright folly or close-fisted ignorance; because by inefficient milling one rejects that margin of profit which in many cases would increase the business standing of the industry, and the harmonious working of those whose livelihood it is.

Re-treating Tailings will be Difficult

The problem that will unquestionably come up at a later date will be the possibility of re-treating tailings to recover the fibre left in them. Asbestos in its mill grades is not a particularly high-priced product, and so it will be very questionable if the revenue from such re-handling of tailing dumps can be profitable. In some cases where milling has been carried out in only a slipshod way, the fibre content might be sufficiently high to pay its way if the market price for such grades of fibre were to appreciate considerably. On the other hand re-handling tailings might never be a profitable proposition; but preventing the loss of fibre would make such re-handling unnecessary.

A Plea for Economy

At a recent lecture before the Royal Society of Arts, Sir Richard Redmayne, Chairman-Governor of the Imperial Mineral Resources Bureau, pointed out the possibility of the exhaustion of certain minerals within the British Empire during the next few years, and while this possibility may be remote with regard to asbestos, yet it is only fair to mining companies and everyone else, that operators do their best to stop both the wasteful or inefficient mining and milling of any mineral.

The milling of asbestos is essentially a mechanical process, and like similar mechanical problems its efficiency can be raised to an economical standard. The present losses can be greatly reduced by both mechanical and electrical means. Reduced losses and increased production are what all should work for, since the attainment of these objects brings both a financial reward and the satisfaction of a job well done.

A fibre and dust-covered countryside, a mountain of tailings here and there containing asbestos fibre to the value of millions of dollars, the ultimate recovery of which will probably prove unprofitable, are not the legacies to hand on to posterity, who might with every justification refer to them as the monuments of the inefficiency and folly of the engineers and mine proprietors of this decade.

PERSONAL AND GENERAL

Mr. S. N. Graham, who is doing field work for the Anglo-French Exploration Company, recently returned from a trip to Rouyn Township in Northwestern Quebec, and has again taken to the field after a week in town.

Mr. Harry Stewart, Manager of the Crown Reserve Company, has been forced by ill-health to leave on an extended holiday. Maurice W. Summerhayes, Consulting Engineer of Toronto, will be in charge of the Company's property during Mr. Stewart's absence.

Mr. E. R. Wood, one of the best known financial men in Toronto, was recently appointed a director of the Northern Canada Power Company. Mr. Wood is President of the Dominion Securities, Limited, who recently purchased a $1,500,000 6½ per cent first mortgage bond issue, which is a joint obligation of the Northern Canada Power Company, the Lower Sturgeon Power Company and the Quinze Power Company. Of the proceeds approximately $3,000,000 will be used in the development of 20,000 h. p. at the Quinze, and $1,200,000 for the retirement of the Northern Canada Power Company's bonds due next January, and the balance for the completion of the Lower Sturgeon plant.

Mr. Newton W. Emmens has been elected a Member of the Association of Professional Engineers of the Province of British Columbia (Mining) and has been retained by the British Petroleums Limited (of Canada) as their Petroleum Engineer and Technical Adviser. Mr. Emmens has recently examined and reported on their leases and operations in the Wainwright field of Alberta. His headquarters are in Vancouver.

J. A. DRESSER DISCUSSES MINING INVESTMENT

The *Financial Times*, Montreal, has stimulated some public discussion on the question of investment in mining securities by the small investor—a matter that is of prime importance to the mineral industry. To last week's issue, Mr. John A. Dresser, President of the Canadian Institute of Mining and Metallurgy, contributes the following letter:

The Editor, The Financial Times:

Sir,—In response to your invitation to take part in the discussion of the position of the small investor in regard to mining enterprises, I would say that the subject is a timely one. In both the east and the west of Canada interest in mining is active and is promising substantial results. Besides the operation of established mines, the pioneer work of prospecting is being prosecuted vigorously, and in consequence there is increasing opportunity for the use of capital, especially in new mining projects.

Your question as to how the small investor may judiciously share in such enterprises has been well introduced by W. M. Goodwin, the editor of the *Canadian Mining Journal*. In a letter to your columns of May 26th. Mr. Goodwin points out that the small investor who cannot afford to thoroughly investigate for himself the projects offered has at best only a random chance of success. Although willing to take a fair share of risk, providing good faith is assured, he is without fair opportunity to inform himself and really only takes chances.

This, of course, is not investment, nor even reasonable speculation. He suffers, too, from a popular idea that any degree of security in mining undertakings is impossible. This belief is probably due in the first place to experience and observation of enterprises of a needlessly ill-judged character, and secondly to unfamiliarity with the means available and the steps necessary to value a mining investment. It may also be fostered by unaccredited salesmen who either do not know better, or do not want their enterprises investigated. Yet, as a matter of fact, a body of ore can in most cases be proven as to its content and value as definitely as the bases of other commercial enterprises, and when so proven is an asset certainly of no less security than a timber limit or a stock of merchandise.

As a safeguard for the small investor, Mr. Goodwin suggests some form of co-operation between established brokerage houses on one hand and reliable technical advisers on the other in order to provide adequate investigation and information for the investor. It is not clear why co-operation between various financial houses should be advised, unless in cases requiring greater financial effort. Otherwise divided liability may mean either divided counsel or lessened responsibility and attention.

As to the other features of Mr. Goodwin's suggestions, there can be no dissent, they appear to be only a general application to mining undertakings of the practice of responsible houses in the case of their commercial enterprises, as the promotion of power developments, manufacture or mercantile projects.

It is common knowledge that in Great Britain or in the United States, for instance, certain brokerage houses have successfully specialized in mine financing, and have retained public confidence. Even in Canada mining operations are sometimes conducted by some of these firms, through the joint action of their financial and their technical staffs.

It is rather rarely that established Canadian brokerage houses take up mining issues in Canada. But it may be in time that they could do so to a greater extent, and with both profit to themselves and greater security to those who wish to apply small sums to legitimate mining operations. This, and whether or not there is sufficient capital in such hands as to warrant undertaking such a course on a broad basis, are questions for the financial rather than the technical man to answer. If feasible, and carried out in a thorough and duly precautionary manner, it would be constructively in the public good.

Lastly, would the small investor avail himself of the opportunity to place his money with greater security, and consequently with less extravagant promise of profits, or would he still favor the lurid dreams of the wildcat promoter?

Yours faithfully,

JOHN A. DRESSER

Montreal, June 26th, 1923.

FIRE!

The Granby News, a little weekly published by the Anyox Community League at Anyox, B. C., has the followwing striking appeal in a recent issue:

Little cigarette butts,
Ashes from your pipe,
Dropped without a thought, belike,
Where the mould is ripe:
Any little sparklet—
The match you throw away,
May cause a conflagration
You'll rue for many a day.

So sings a fellow worker in a minor key to a nursery rhyme measure. But as good things sometimes come in small packages, there is no reason why there shouldn't be more truth than mere metre in the tenor of such a song. There is; in fact it is all truth, and it would be well for everyone of us to recognize it as such, learn the words of the song and sing likewise. On three occasions the employment of every man in Anyox has been jeopardized by the fire fiend going on a rampage, blazing in all directions, and crowding the residential section as well as the units of production. This may occur again this year, and the thing be accomplished if it gets the proper impetus, no matter how big the effort may be to curb and control the element. The season of summer is with us now, and the excessive heat of the early part of the month brought the fire risk mighty close to us all with remarkable suddenness. There is really no excuse for fires whatsoever; they are absolutely unnecessary except to warm us and drive our machinery, and occur only through the agency of man or a great convulsion of nature. Natural causes contributing to the punishment of the world by fire are of rare occurrence and are beyond our control; but the man-caused fires, which from time immemorial have been responsible for great suffering and tremendous property losses, can be practically eliminated by taking advantage of the sure means possessed by each and every average one of us—the faculty of common sense. Let us cultivate this faculty to the utmost, and it will surely follow that carefulness will creep into our mental councils and be productive of much that is good. Just think about it; and outside of our kitchen stoves let's have a fireless summer.

CONCRETE HEADFRAMES

The new headframes erected at the coal mines in the north of France to replace those destroyed during the war are quite generally made of reinforced concrete. There are numbers of these to be seen now in the regions round Lens and Bethune.

THE QUEBEC MINING REPORT FOR 1922

The final report of the Quebec Bureau of Mines for 1922 is an unusually interesting and useful volume. The statistics for the year have already been presented in preliminary form, and show a mineral industry almost wholly dependent upon non-metallic production, principally asbestos and structural materials. The steady production of the Derry feldspar quarry in the Buckingham district is a bright spot.

An outstanding feature of the report is the definite warning it gives to investors in the pages devoted to "Mining Ventures and the Public." Mr. Denis has followed with good effect the lead given by Mr. Taschereau in warning the public of the crooked mining stock promoter and salesman, and his description of "the insidious literature and glowing statements of agents offering mining shares and beautifully engraved certificates" goes to the mark. The whole statement is very discriminating, and deserves wide circulation in the public press.

Another section draws attention to the various areas of mineral-producing rocks, variously designated as Keewatin, Huronian, etc., scattered throughout the vast areas of granitic rocks in northern Quebec. It is to these areas that prospectors should direct their attention.

The asbestos industry made a notable recovery during the year; but it appears that, in spite of a reduction in price of almost one-half, there is still difficulty in disposing of crude fibre. It is noted, however, that, whereas the sales of crude (long fibre) asbestos from Quebec increased from 6,316 tons in 1921 to 9,047 tons in 1922, the shipments of Rhodesian asbestos continued to decline, being 15,958 tons in 1922 against 21,872 tons the previous year.

Copper mining in the Eastern Townships has ceased, due to the availability of low-priced sulphur for the manufacture of sulphuric acid, for which purpose the copper pyrites was used. There is, however, a new and promising copper occurrence at the headwaters of the York river in Gaspé, which was examined by an officer of the Bureau. Very little work of development has as yet been done on these claims.

Dr. F. J. Alcock's report (Summary report, Geological Survey, 1921, Part D.) on the Gaspé zinc-lead deposits is reproduced in part in this report. Road-building constituted the chief activity of the Federal Zinc and Lead Company during the year.

The principal interest in the report centres on Dr. H. C. Cooke's report on part of the new gold area of northwestern Quebec, which is here published for the first time. While a large part of this report is devoted to the geology of the region, explicit and useful directions are given to prospectors.

The graphite industry continues to languish, due to the war-time stocks in various producing centres that continue unsold, and are being disposed of, it is said, at less than their present cost of production. Not until the price of graphite goes up to a normal figure will it be possible to operate profitably in the Buckingham district, where one of the properties is equipped with a modern mill, ready for operation.

The final section of the report is devoted to a discussion of labour conditions and mine accidents. "It is gratifying to report that there no labour troubles in the Quebec mines in 1922." Mine accidents were at a rate of 46 per thousand men employed, while fatal accidents were at the rate of 2.72 per thousand.

A new tin smelter was put in operation in May at Sydney, Australia, By O. T. Lemprière & Co.

THE IMPERIAL ECONOMIC CONFERENCE

An Australian View

The subjects listed by the Colonial Office for prime consideration by the forthcoming Economic Conference indicate that the present British Government is more alive than any of its predecessors to the necessity of entering into co-operation with the Dominions to promote trade within the Empire. The first five questions scheduled for discussion on the official programme are as follows: — (1) Ways and means of full development of the natural resources of the Dominions, (2) Inter-Imperial commerce and shipping communication generally (3) Co-ordinate action and improvement of technical research (4) Organization of economic intelligence, and (5) Unification of the law and practice in the Empire in matters affecting trade development.

Read in the light of the fact that Great Britain intends to propose an enlarged scheme for the settlement of her surplus population in the Dominions, the items set forth above suggest that she is ready and willing to give sympathetic consideration to the question of reciprocal trading preferences. Britain is now in the position (largely as a result of the war) of being unable to provide employment for her whole working population . The taxpayers of the United Kingdom are feeding upwards of 1,500,000 workers for whom the country is unable to find occupations; but although during the last few months Britain's foreign trade has substantially revived (leading to a great expansion in her manufacturing activities) there is no discernible prospect of improving her industrial situation sufficiently to absorb more than a proportion of the workless mass. In these circumstances her rulers have realized the necessity of transferring the surplus population to countries able and willing to put their services to economic use. Inasmuch, however, as their emigration to foreign lands would weaken Britain without any compensating gain to any part of the Empire, the Imperial Government is most anxious to provide for their settlement in the Dominions.

The Dominions, for their part, are all anxious to increase their vital strength, and would greatly prefer immigrants of their own kin to all others. No Dominion, however, nor all together, could undertake making homes and finding occupations for the large numbers of prospective British immigrants whose fortunes are at stake unless adequate assistance were forthcoming from the Mother Country to assure the future of the immigrants when settled in the lands of their adoption. The Dominions, primarily, are food producing countries. During the last few years they have all (and Australia particularly) developed the secondary side of their industrial life, but not one of the Dominions has yet acquired the capacity to absorb any great or sudden influx of people in its manufacturing activities. Primary production, however, offers an illimitable field. At the present moment, in the whole range of the British Empire, there are only 13,000,000 white agriculturists. When we remember that there are 18,000,000 agriculturists in France and 20,000,000 in Germany, and when we remember further that Britain is dependent on the outer world for more than half her food requirements, it is obvious that a vast scope is offering within the Empire for the development of primary production.

In view of the decidedly sympathetic attitude that Britain is now displaying to the cause of Empire

development, there is real hope that the forthcoming Economic Conference will find a solution of the problems indicated. At previous conferences these problems were at best imperfectly understood, and the sacrifices which the Dominions had made to that end or were prepared to make were disparaged or disregarded. There has been a great awakening in Britain since the war, and not one of her statesmen to-day evinces any disposition to "bang, bar and bolt the doors of Britain" on the trade of the Dominions. On the contrary, they are displaying a lively appreciation of the necessity to discover and enforce a formula of close Imperial co-operation, and they have already give some indication of their conversion to the policy of reciprocity by granting certain tariff preferences to some of the products of the Dominions.

The Commonwealth Government has announced that it will press the necessity for greater preference very strongly at the Conference. We hope that it will succeed. Most economists are agreed that in co-operation and reciprocity resides the surest hope for the solidification of the British Empire, and for its development into the mighty, self-contained, economic fabric which Nature, in her lavish bestowal of her richest resources, seems to have marked out as its destiny. — Industrial Australian and Mining Standard.

A METHOD OF UNWATERING AN OLD PROSPECT SHAFT*

A property was to be examined. It was a prospect in the early stages, and there was beside the usual trenches and assessment-pits, a shaft 125 feet deep, with an 80 foot drift at the hundred and two small overhead stopes above the drift. These workings contained water to within 40 feet of the collar. In addition to removing the water in the workings there was an inflow of 5 gallons per minute which would have to be contended with.

The hoisting equipment for sinking the shaft had been removed, with only a head-frame and its sheave wheel left. To have secured a hoist, even a used one, transport it from town (35 miles), set it up and then, when the unwatering had been accomplished, return the outfit and place it on the market, was an expenditure that would have made the examination an expensive affair. An automobile was essential to convey our party to the property and it occured to us that the mine water might be removed by bailing, with the car, on a "whip."

A 50-gallon iron sinking bucket, and 250 feet of 5-16 wire rope were rented. A hinged trough, and dumping chain, were rigged at the proper elevation in the head frame. The cable was attached to the channel-bar frame of the Dodge car. The cactus and brush were cleared to make a run-way upon which the auto could travel forward and backward to and from the head-frame while journeying the bucket up and down the shaft. The car was faced toward the shaft so that it would be in reverse gear when raising the load. Rocks were put in the tonneau to weigh down the rear wheels. The headlights, together with a shielded lantern in the head-frame, provided adequate illumination for night work. A laborer at the dumping trough was the only hand required beside the auto driver.

Thus equipped and manned, operations were commenced. Without slipping the tires, the car was able to raise the fully loaded bucket of 500 pounds, including the cable, and would do so very smoothly if the bucket were allowed, before the pull and after having filled, to submerge a couple of feet, thus giving the car a start before the bucket reached the surface of the water. Havig raised the bucket into the head-frame, the dumping chain was attached to the ring under the bottom of the bucket, the load eased down, dumped, and picked up again, all without a shift of gears. The weight of the bucket was sufficient to move the car back toward the shaft. However, to hasten the matter, the gear was shifted into forward, low, a kick-off given and then a coast and a breaking as the bottom was approched.. The dirt runway was sprinkled every hour for the first six, and then every two hours. A hard-packed road was early made, and maintained.

Because of the inflowing water, steady operations were desirable. After the first part-day of try-out, the operations were continuous.

We pulled 76,000 gallons of water in 34 hours of hoisting, making as high as 3,000 gallons an hour at times. This work consumed 23 gallons of gasoline, one of light oil and one of heavy.

The shaft was drained, the bottom mucked out and sampled. The hoisting service proved to be a safe and very helpful adjunct to the sampling job.

It is obvious that the cost of this unwatering was decidedly low.

* From Colorado School of Mines Magazine.

INDUSTRIAL ITEMS

The Turbinair Hoist, double drum type, "HDA," of the Sullivan Machinery Co., is described in a comprehensive way in Bulletin 76-D, available on request. The construction of the hoist and its performance are noted, and its many effective uses illustrated and described, particularly "slushing" in mines. Suitable types of scrapers are illustrated by means of drawings. The uses of the single drum type, "HA," are similarly described in Bulletin 76-C.

"Sales Schools" are a recent development of the Link-Belt Company. New salesmen are gathered from the various sales branches at a central point, and these are instructed in their work. They likewise gain a personal acquaintance with the heads of departments and are able to inspect the company's factories and products at these meetings. The third Sales School was conducted early this month in Indianapolis. The former schools have proved to be a paying investment, and no doubt this one will be the same.

The Canadian Ingersoll Rand Co., Montreal, have just issued a new descriptive bulletin covering their Cameron double suction, volute centrifugal pumps. The illustrations are numerous and clearly set forth the special features of these pumps, while the text contains much useful information on the mechanical details, tests, dimension table and part list. The book is known as No. 7350-C, and will be forwarded to anyone interested on application.

TOURMALINE

When in fine pink, red, or green crystals, tourmaline is of value. Gem tourmaline may be found in pegmatite dikes, and at the contact of intrusive granite with crystalline limestone, schists, and gneiss. Crystals of brown tourmaline of gem quality have been found in crystalline limestone in Ross, Ontario, and at Calumet Falls, Clarendon, and Hunterstown, Quebec.

COAL STATISTICS FOR MARCH

The monthly report on coal by the Dominion Bureau of Statistics shows that the output of coal from Canadian mines during March amounted to 1,457,000 short tons, a decrease of 11% from the figures for the previous month but an increase of 12% over the average for the month of the preceding three years. The output for the month in Alberta showed a decrease of 202,000 tons and in Saskatchewan 2,000 tons while the output for British Columbia was the same. Nova Scotia and New Brunswick showed increases of 24,000 tons and 3,000 tons respectively. The cumulative output from all mines for the three months of 1923 amounted to 4,858,400 tons. This figure against the three-year average for the period showed an increase of 22 per cent.

Comparison of the March and February figures covering the importation of coal from the United States and Great Britain showed an increase of 37 per cent. March imports amounted to 1,817,700 tons while the February figure was 1,326,200 tons. The March importations this year were 28 per cent greater than the preceding three-year average for the month. Imports from Great Britain amounted to 22,000 tons during the month. Total importations of all coal for the three months of 1923 was 4,785,600 tons, an increase of 33 per cent above the three-year average for the period.

The imports of anthracite for March totalled 493,400 tons. This figure was 17 per cent higher than that of February and 22 per cent higher than the three-year average for the month. A classification of these imports showed that 442,800 tons of egg, grate, stove, etc. sizes was obtained from the United States and 6,700 tons of the same sizes from Great Britain. The balance of the anthracite importation was of buckwheat and rice sizes, industrial fuel, amounting to 43,900 tons. Of the total anthracite imported during January, 323,000 tons was entered through the ports of Ontario and the balance through the ports of eastern Canada. The total amount imported during the three months of 1923 was 1,337,500 tons, an increase of 34 per cent over the three-year average for this period.

The exports of Canadian coal for the month of March showed an increase of 54 per cent over February figures, the quantities being March, 284,500 tons, February, 185,000 tons. Comparison of the March exports with the preceding three-year average showed an increase of 41 per cent. Exports from the eastern provinces amounted to 146,500 tons, an increase of 59,400 tons over the February exports; those from the western provinces amounted to 138,000 tons an increase of 40,100 tons over February. The cumulative exports for the year to date amounted to 685,600 tons, or is 29 per cent greater than the three-year average for this period.

The tonnage made available for consumption in Canada during March was 2,990,600 tons or 8 per cent more in February when 2,778,400 tons was made available. In comparison with the three-year average, the March tonnage showed an increase of 19 per cent. The total coal made available in the first three months of 1923 amounted to 8,958,400 tons and for the twelve months ending March 31st; 29,419,300 tons. These figures are respectively 27% greater and 8% lower than the three year averages for the same periods.

The total number of men employed in the coal mines of Canada during March was 31,077 of whom 23,228 were underground and 7,849 surface men as compared with 24,075 and 8,222 on surface for February. The production per man was 47 tons for March as compared with 50 tons per man in February. The coal mines of the western provinces suffered severely from lack of orders, a factor which was practically negligible in the east.

NICKEL MINING IN NEW CALEDONIA

The nickel deposits of Noumea occur in serpentine country rock, as do chrome and cobalt as well. There is a somewhat different aspect in the rock containing these metals, so that to the experienced prospector it is easy to know what is likely to be found where he happens to be working, though the writer knows of a body of chrome ore intruding just alongside a large body of nickel ore.

The nickel ore-bodies are found mostly on ridges, the garnierite showing green on the surface, this ore having at first attracted prospectors who were under the belief that they had found copper ore. For some time this green ore was exclusively looked for, and underground mining was resorted to in following the shoots. Later it was found by assay that the dump contained rich ores, in some cases richer than what had been retained for sale. As a matter of fact, nickel mining is mostly an open cut or quarrying proposition, using benches at various levels.

As a rule the ore-bodies are so soft that pick and shovel are the only tools required to begin with. Of course, as work progresses in depth the material hardens, the formation taking a shingly character. Though dynamite is extensively used, it certainly is not the explosive wanted as a general rule. The workmen prefer dynamite, the main reason being that part of the charge is very often kept back in order to be used for fishing purposes. In fact, a large trade in dynamite is done in an illicit way to provide fishermen with their wants in this respect.

It is necessary to test ore values by assay as work progresses, for the percentage of metal varies considerably, and the eye cannot discern the change. The density alone is not a dependable guide, light ores sometimes testing well and heavy ore being poor. The organization of the work is faulty, the ore in some cases being handled many times before being disposed of, and very few of the workers would satisfy the average railway foreman in the use of the shovel.

The ores are now seldom exported, two local smelting works producing mattes, while a third one, controlled by Japanese, has been partly erected; but the finishing touch has to be given, the work being suspended for some time, and at present there is no sign of a move towards its completion.

The nickel deposits of Noumea are of considerable extent and, no doubt, they will be, to this island, the main means of industrial prosperity for years to come, particularly if the metal has new uses, and its metallurgy is simplified. To the writer there seems a possibility of nickel metal being produced on the same lines as copper and at the same price, in which case its industrial future should be exceedingly good. The ores worked range from 5 per cent. upwards; lower grades are put on the dump. The last quotation seen by the writer was 790 francs per 100 kilos, which gives a 5 per cent. ore a value of somewhat about 300 francs for metal recovered. — Industrial Australian and Mining Standard.

The long-continued coal strike in New South Wales has resulted in a shortage of coal, and the State government has begun to distribute its surplus stocks to users.

GEARS

A Description of the Various Kinds, their Characteristics and their Use

(Courtesy of Hamilton Gear and Machine Co., Toronto)

(Continued from page 500)

Gear Drives vs. Belts

Gears should be used on many drives now equipped with belts. There is no doubt of the advantages of belts for long spans or the safety features of slipping in case of a jam; but it is impossible to predict at exactly what load a belt will slip, so if it is designed to have ample capacity under all loads, it is almost sure to have too much slip if conditions are good. A soft metal shearing pin used in connection with a gear drive gives the ideal combination for safety and positiveness.

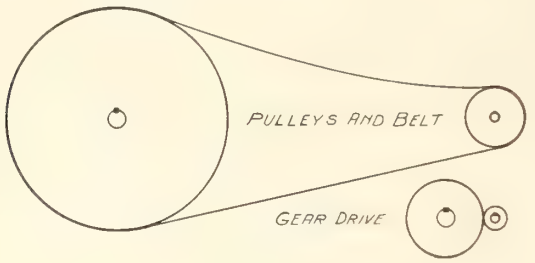

Fig. 7.

The diagram above shows the relative size of a gear and a belt drive of the same capacity. Also the gears would only be about one-third as wide as the pulleys. The saving in space is great. Gear drives are safer than belts because on account of their small size it is much easier to guard them effectively. The guards on a gear can frequently be made to form a complete enclosure containing an oil bath. This will promote the efficiency of the drive to such an extent as to be a paying investment of itself, so that the safety guard really costs nothing extra.

As a rule gears are more durable than belts, and, for the service they perform, are far cheaper in the long run. There is much less load on the bearings with gears, for belts only transmit power in proportion to the difference between the tensions on the tight and slack side. There is no fire risk with gears like that arising in dusty locations with belts, from static sparks or friction from rubbing against guards.

The saving of valuable space by the use of a compact gear drive is often of prime importance. Gears, especially rawhide pinions, or in large sizes the herringbone gear drives, lend themselves especially well to the individual electric motor drive in industrial plants.

Gears are more efficient than belts, due to the absence of slip and creep. Creep is always present in belts and slip usually so. With gears there is no slip, therefore no loss. The best way to get rid of your belting troubles is to replace the belts, wherever possible, with gears and plan to use gears on new drives.

Double-Helical Gears

The operating advantages, the smoothness, speed and strength, that may be obtained with this type of gear have definite mechanical reasons back of them. These are not as generally understood as they might be and the following is an explanation of some of the basic principles.

"Continuous Action" is the fundamental feature. The face of a correctly designed gear is wide enough so that the slant of the teeth allows each to overlop its neighbor by at least a small amount. That is, the

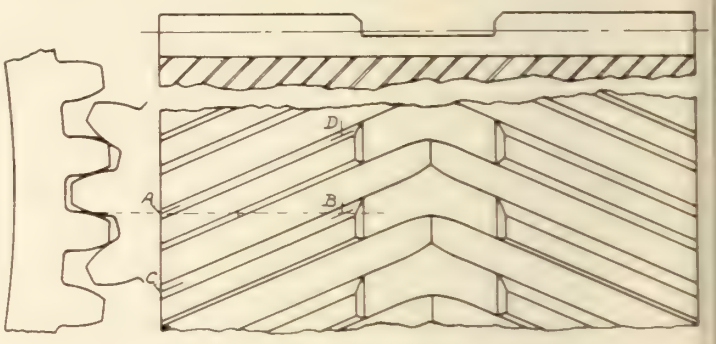

Fig. 8.

(half) working face is made greater than A B. Whatever condition of mesh exists at A is duplicated at B. C would be one pitch earlier and D one pitch later, and all along the faces of the teeth A D and C B, every point would represent a different condition from first engagement to recession. At any given instant the line of contact between a gear tooth and a pinion tooth would be a diagonal across the face of the tooth from near the root at one end to near the top at the other. This, of course, eliminates shocks and permits high speed with maximum strength and durability.

The two sections of the gear, right and left hand, are necessary to balance the thrust. It is immaterial whether the teeth are located opposite or staggered though the former is usual. There are carefully worked out standards for the angle, the minimum face and the groove width.

Note that there is no more sliding action with double helical gears than with spurs. The action is just as truly a rolling motion and not at all like a worm or spiral.

Mounting and Adjustment of Bevel Gears

Proper adjustment of bevel gears is a vital factor in obtaining quiet operation and durability. Backlash of about .012 inch per inch of circular pitch is desirable. The bearing surface under full load should be at about the pitch line and along the full length from heel to toe, but on account of spring in the shafts in the usual "over-hung" pinion mounting, it is necessary to show a toe contact when testing with a light load or on a testing stand, in order to get full bearing when loaded. The weaker the mounting, the shorter the contact should show, five-eights of the length of the face for average conditions, or nearly full length where the pinion is very rigidly supported. (Fig. 9).

First, set up with teeth flush at the large end, apply red lead and run. If correct, the marking will show

as in Fig. 1. If a cross-bearing shows (Fig. 2) there is an error in gear cutting or in the level of the shafts. Now adjust relative shaft heights. If there is a toe bearing over half the length on the driving side, they

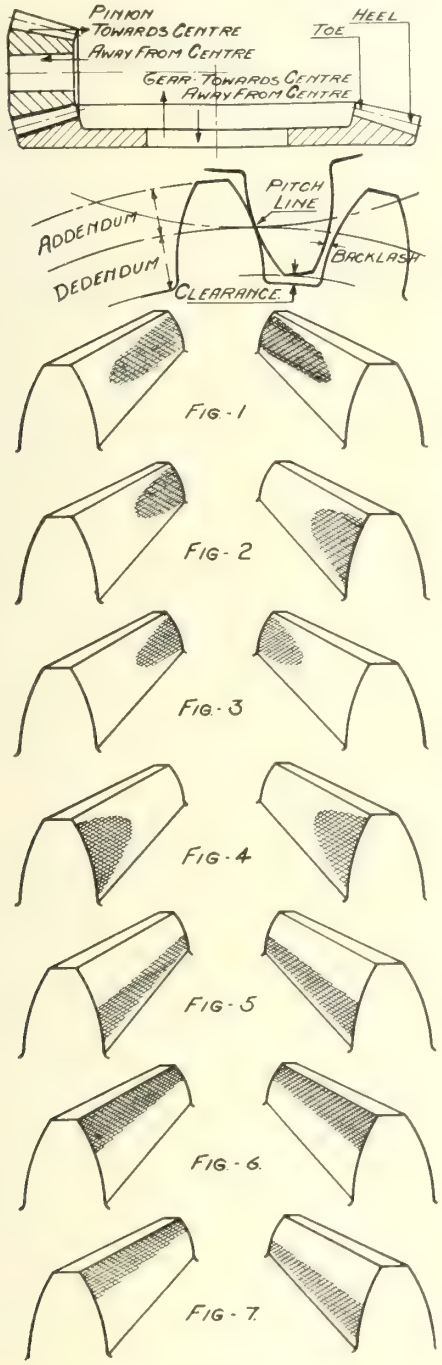

Fig. 9.

are usable, but not so with a heel bearing. If a toe bearing shows on both sides but is too short (Fig. 3) move the gear away from the pinion. If a heel bearing shows (Fig. 4), move the gear towards the pinion.

The position of the bearing up or down the tooth profile is adjusted independently. If the bearing is low (Fig. 5) move the pinion backwards from centre. If the bearing is high (Fig. 6) move the pinion towards centre. These movements will alter the lengthwise position of the bearing and several adjustments may be needed. A lame bearing (Fig. 7) shows errors or wear in the teeth. Such gears can be adjusted to give a fair bearing on the drive side but a bad reverse.

Spiral Gears

The consideration of direction of rotation of driver and driven in a pair of spiral gears, and the direction of their respective thrust pressures, are often very puzzling to one who is not continually handling such gears.

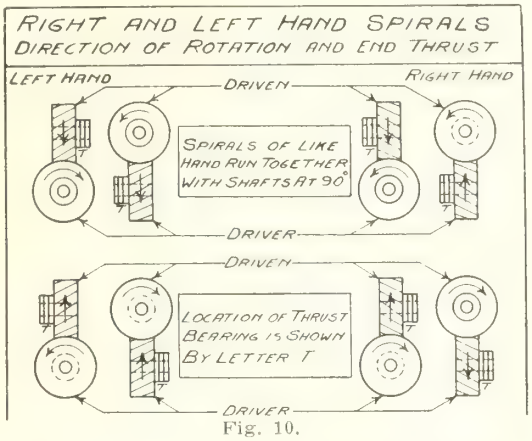

Fig. 10.

In this connection the above may be helpful. The arrows show plainly the direction of rotation, and the location of the thrust bearing is also indicated on the proper side of the gear. These thrust forces, acting in a direction parallel to the shaft, must be taken account of whether the driving or the driven shafts are parallel or at an angle.

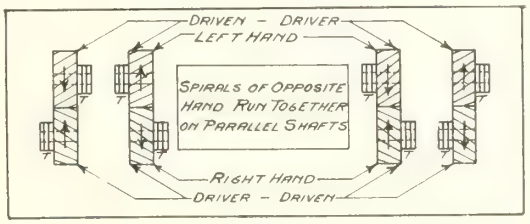

Fig. 11

Double helical gears, with shafts parallel (not shown), are composed of a right and a left hand helical section and thus balance their own thrust, so no external bearing is necessary. This is the very highest type of gearing and is recommended for all high-speed, heavy duty drives.

SUCTION GAS PLANT USES WOOD FUEL

It is well known that the most economical method of generating power from fuel is by use of the gas engine. The Lonely Mine, 43 miles from the railway at Buluwayo in Southern Rhodesia, has solved its power problems by this means. It had formerly a steam plant using 3,000 cords of wood a month. The present suction gas plant delivers the same power with a consumption of 600 cords a month. The plant is designed specially for the use of wood, and comprises four units of 350 h.p. each, with Crossley gas generators and Premier multi cylinder gas engines. Green timber can be used effectively in the gas producers.

ALCOHOL FROM CALCIUM CARBIDE

It has been suggested that alcohol can be manufactured cheaply from calcium carbide. Already acetic acid and acetone are made thus, and it is quite possible that further researches will show that alcohol also can be made in this way.

The use of petroleum as an illuminant dates from 1855, when an American professor first distilled it into fractions suitable for various uses.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

Porcupine — There has been a temporary cessation of power in the Porcupine district on account of bush fires, but it only lasted about a day. The extended dry season resulted in a fire situation that was beginning to be quite dangerous, and that did result in burning out a short section of the transmission line. The fires were close to the town of Timmins when a change of wind and a moderate amount of rain removed the menace. The fire situation in the vicinity of the Rouyn district of Northwestern Quebec was also reported to be dangerous, but conditions are understood to have improved there as well.

The Dome is understood to have taken an option on the McIntyre claims in Gauthier township. This year the company has a very large and active exploration department and is putting scouts in practically all the active districts of Ontario, as well as having taken options on a large number of claims in the Rouyn district.

The West Dome Lake Consolidated has been unwatered to the 300-foot level, and this work will be continued to the 600-foot level. It is hoped that when that point is reached sufficient electric energy will be available to permit the shaft being continued to the 1,000-foot level.

McIntyre's production is understood to be running at the rate of approximately $300,000 a month, of which 50% should represent profit. If this rate can be maintained, there is every expectation that the dividend rate will be increased in the near future. The company's fiscal year ends June 30th, and it is possible that some definite action will be taken following the annual meeting. The present dividend rate is 15%. Mine development continues to be satisfactory, and there is a general feeling that McIntyre may prove eventually to be the most important mine in the district.

The Hollinger Consolidated is understood to be considering the installation of a Diesel oil engine of 1,200 h.p. in order to provide for the expected power shortage next winter, and to carry the company through the period of low power until the time when its own development on the Abitibi River will be ready. The bids for the construction of the 20,000 h.p. installation on the Abitibi River have all been filed, but so far no information regarding them has been given out. At the present time the company is generating 800 h.p. by steam and the mill is treating approximately 4,500 tons a day. According to the reports of the Northern Canada Power Company, the Dome, Hollinger and McIntyre are receiving the largest supply of electric energy in their history. Within a few days the Hollinger should be able to do without their steam power, as the Lower Sturgeon plant is now developing over 3,000 h.p. This will permit the Hollinger, in particular, to increase its mill output, and it is believed that within a comparatively short time the company will be treating about 6,000 tons a day. The regular four-weekly dividend of 1 per cent. has been declared, payable July 16th to shareholders of record June 28th.

Two shafts on the Ankerite property have been unwatered and the water is expected to be out of the main shaft within a short time. The property is now owned by the North American Gold Corporation, which has already put machines to work.

A meeting of the shareholders of the Porcupine-Davidson Gold Mines has been called for July 22nd to ratify by-laws proposing the sale of shares at a discount.

Kirkland — Production at the Teck-Hughes is running at the rate of approximately $100,000 a month, and there is good reason to believe that this rate of production can be maintained. Work on the 1,100-foot level is understood to be very satisfactory, and unofficial reports are to the effect that at that level the best ore of the mine has been opened up.

Col. Gear, president of the Crown Reserve, states that the result of drifting on the 550-foot level of No.1 vein at the Larder Lake property has been very satisfactory. Thirty feet of drifting shows values of $11.00 to $22.00 over a width of five feet. The vein, however, has a width of approximately twenty feet, and a crosscut is to be started to determine the values over the total width.

At the Northland property, fifteen men are engaged in surface exploration, and a number of veins have been found. A small portable boiler and a steam plugger drill are being used to assist in opening up the discoveries.

R. A. and I. M. Sinclair, contractors of Toronto, have secured the contract for the construction of the Kirkland Lake branch line to the Crown Reserve property. Construction is to be started immediately and steel is expected to be into the Crown Reserve by the end of the year.

A meeting of the shareholders of the Montreal-Ontario has been called for June 26th, to ratify the sale of 400,000 shares of treasury stock. This action is purely formal, as the stock was sold some time ago. No new reports are available regarding the discoveries recently made on the 450-foot level.

Kirkland. — During the month of May the Lake Shore mill treated 1,880 tons of ore, and recovered $53,649.70, an average grade of $28.43 a ton. This is understood to constitute a record month's production in the history of the company, but it is believed that it will be equalled in June.

Matheson — The Croesus Mine, near Matheson, which is owned by the Dominion Reduction Company, has been unwatered to the 100-foot level, and a small amount of mining is being done in an effort to locate further high-grade pockets similar to those found some years ago.

Ontario Mining Association — The annual meeting of the Ontario Mining Association is to be held in Kirkland Lake and South Lorrain on July 5th, 6th and 7th. The business meeting will be held in Kirkland Lake and an opportunity will be offered to visit the different mines of the camp on the 5th and 6th. On the afternoon of July 6th the party will return to Cobalt and on the 7th will go to South Lorrain by automobile.

Larder. — A special general meeting of the shareholders of the Argonaut Gold Mines has been called for July 7th. Delays have been experienced in starting the mill, but it is now expected that operations will commence early in July.

Cobalt. — The recent discovery of the Mining Corporation on the Peterson Lake property is lasting better than was originally anticipated. About fifty feet of drifting has been done, and the vein, while only one inch in thickness, carries values up to 3,000 ounces. It is expected that shipments to the mill will be started shortly.

Winzing operations on the 350-foot level of the Genessee have disclosed some promising ore. In places the vein shows an inch of high-grade ore, which will run 3,000 ounces to the ton. The ore-shoot has been opened up for a length of about forty feet.

La Rose has started sinking the Violet shaft from 635 feet to 685 feet. On the 635-foot level a strong vein has been found which shows, in places, 8 inches of 3,000-ounce ore. Regular shipments of mill ore are being made to the Mining Corporation mill and the grade is understood to be very satisfactory.

During the week ending June 22nd, the O'Brien shipped two cars of ore totalling 127,960 pounds, and the Coniagas shipped one car of flotation concentrate weighing 96,120 pounds.

Quinze Power Contracts — The Quinze Power Company, which is the new company formed by the Northern Canada Power Company to operate the Quinze power recently acquired from the Quebec Government, has been letting a large number of contracts and shows every indication of a determined effort to live up to the promise to have power in Porcupine in 1924. The company has sold its bonds to the Dominion Securities, Limited, of Toronto. It is estimated that the first unit of 20,000 h.p. will cost $3,000,000. Morrow & Beatty, who have built a majority of the large plants throughout Northern Ontario, have secured the contract for the construction work. The generators, electric switching apparatus and transformers will be supplied by the Swedish Electric Company, of Sweden. The Northern Aluminum Company will supply 720 miles of aluminum wire for the transmission line. The Canada Bridge Company has the contract for 972 steel transmisssion towers. The first of these will be delivered in less than two months. The Canadian Porcelain Company of Hamilton has the contract for all transmission line hardware, and the Dominion Engineering Company of Montreal has the contract for the water wheels.

Power Supply — The recent rains have somewhat improved the power conditions in the Porcupine district. It is now reported that the Sturgeon Falls development should be supplying power by July 1st.

Ontario Department of Mines Loses C. W. Knight — Mr. C. W. Knight, Assistant Provincial Geologist for Ontario, is leaving the Government service to accept a position with the Nipissing Mining Company. He has been with the Department for the last nineteen years and is more particularly known for his work in the Sudbury and Cobalt districts. The Department of Mines and the mining industry can ill afford to lose the public services of a man of Mr. Knight's experience and attainments, and of one who has been so closely identified with the development of Northern Ontario. It can hardly be considered a tribute to the head of the Department of Mines that Mr. Knight's position in the Government service should not have been made sufficiently attractive to retain his services. It is well known that the technical men of the department are inadequately paid, and this is a policy with which the mining men of the province have no sympathy. The industry is of sufficient importance and the revenue derived from it is ample to justify decent salries, commensurate to the work that is being done. It is to be hoped that Mr. Knight's resignation may have a salutary effect and that although the Province loses his services, it may react to the benefit of the other members of the staff of the department.

The Provincial Elections. — The recent Ontario elections resulted in a landslide that has seldom been equalled in the political history of the Province. As a result, Hon. Howard Ferguson will be the next Premier and Mr. Chas. McCrea, of Sudbury, will be the next Minister of Mines. This is of particular interest to the mining industry of Northern Ontario, because Mr. Ferguson is generally credited with being the best Minister of Mines that the Province has ever had, and he thoroughly understands the needs of Northern Ontario. Mr. McCrea, who is a lawyer, has lived most of his life in the mining district of Sudbury, and is believed to be a worthy successor of Mr. Ferguson. His appointment will meet with the general approval of the mining men throughout the Province, and it is now felt that this important industry will receive the consideration it deserves, which it has not received during the past several years.

NORTHWESTERN QUEBEC

Interest has been aroused by reports of new finds in Boischatel township and in Duprat township.

Preparations are being made by Mr. Fletcher, in charge, for drilling the Noranda ground in Rouyn. Messrs. Thomson and Chadbourne are on the property, and twenty-three men are employed.

Mr. Charlie Richardson has made another trip to his Rouyn ground, but has not done much work as yet.

William Gowan, for the La Rose; Patrick Meehan, for the Lyman interest; Major Dunlap and James Bartlett for the Coniagas, have small crews in the Pelletier lake section of Rouyn.

It costs $21 to bring a man from Ville Marie into Rouyn; so the expense of prospecting some of the Quebec areas is something pioneers have to contend with.

The recent fires, which advanced on a 25-mile front, burned through Boischatel, starting at the west end of that township, and went within two miles of the Noranda. Many claims were completely burned over. The heavy rains have given more prospectors a chance to enter the bush.

Confusion in the staking of certain claims north of Pelletier lake has enabled men said to represent the Nipissing company to re-stake them.

Dr. Thompson has opened an office on Osisko lake and is prepared to care for men at the respective prospects on a basis of $1 per month per man. He was formerly connected with Dr. Arnold of Haileybury.

The transportation system between Ville Marie and Pelletier lake is intolerably poor. The service is irregular. It is a common thing to have to wait for days at Sturgeon Point, German Point, or Gillies Depot, for a boat. One engineer who paddled out 16 miles to German Point, rather than wait for a boat there paddled another 45 miles to Sturgeon Rapids, found a boat there, and then had to wait at Gillies; so he chose to hire an auto from a farmer, at a cost of $12, in order to reach Ville Marie. Such facilities for transport are not calculated to hasten work.

There is no telephone communication between Gillies and Ville Marie. There is a Government telephone line, but it is out of order, and has been so for three weeks or more.

With a regular schedule the trip from Ville Marie to Pelletier or Rouyn could be made in a day, instead of three or four days, as sometimes happens.

The fire made a ready-made roast moose for a party at Lake Fortune. It also wiped out the ice house, where the moose reposed.

The Noranda has several pits sunk on their ore bodies and wish to know more of their Powell vein at depth; hence the present use of the diamond drill.

Though transportation conditions are somewhat inadequate and annoying, and the black flies have been insufferable, and the cost of taking labor in to the fields is excessive, it is the greater tribute to the enterprise of those with working forces that they are making progress.

NOVA SCOTIA

The U. M. W. A. Convention. — Some time ago the *Canadian Mining Journal* made the statement that everything would run smoothly at Nova Scotia collieries, should there be no election of U. M. W. officers until December. It was foreseen that an election might take place during the summer months, and as District No. 26 has become more of a political than a labor organization, election issues would be sure to bring about considerable trouble. The election has come, and with it a threat of strike, if the 1921 rates are not paid. This demand was made from a convention held in New Glasgow, when a telegram was forwarded to President Wolvin demanding the payment of these rates. The reply was in the negative, and went on to state that "the Company were satisfied with the present rates, that they had made their contracts under them, and any increase in wages would result in large financial loss to the company."

It ought to be noted that the 1921 rates are the war-peak wage rates, when the cost of living was high. With the present much reduced cost of living, it is hard to understand why these rates should be so strongly urged. During the war the United Mines Workers, when approaching the Dominion Coal Company for any increase in wages, used the increased cost of living as one of their strongest arguments. It was a very plausible argument, and also very successful. But just as soon as the cost of living began to fall and the company began to reduce wages, the question was asked by the United Mine Workers, "What has the cost of living to do with wages?" It has much to do with it, every way. There might be some justification in asking for the 1921 wage rates if the cost of living had remained the same as in 1921. But there can be no reasonable argument in favor of 1921 wages when the cost of living is much below what it was that year. There are two ways of increasing wages; one is to give a straight increase, while the other is to reduce the cost of living. This latter has been done and the present wage rate at the present cost of living is equal to, if not larger than, the 1921 rate. If the United Mine Workers succeed in their present attempt to increase wages, the purchasing power of their earnings will be far beyond that of any other time in the history of mining in Nova Scotia. While they may be only receiving the 1921 rate, yet the increase gained will be equivalent to the difference in the cost of living between 1921 and the present time, which is about 48 per cent.

President Lewis Takes a Hand.—There is another side to this question, of far more importance than the financial side, serious as that is. It is the moral side. That the Executive of any labor organization should enter into any wage agreement to last for a certain period and then openly advocate its violation when only half completed, shows a state of moral degeneration that can be viewed only with alarm. These men seem to be determined to demoralize the miners of Nova Scotia, and up to the present, they have been fairly successful in their aims. But now it seems that they have reached the length of their tether, and that President Lewis is endeavoring successfully to curb them. Finding that the District Convention was determined to have a strike, President Lewis wired them as follows:

"Indianapolis, June 22nd, 1923.

"Dan Livingstone, President, District 26, United Mine Workers of America, New Glasgow.

"International Executive Board has considered your telegram of June 21st stating convention of District 26 considers agreement with coal operators as being now null and void.

"This action is an unwarranted violation of the traditions and consistent policies of the United Mine Workers, which believes in the integrity of contracts and strict adherence to its provisions by all parties thereto. No district of the United Mine Workers has ever repudiated a joint agreement after it had been accepted by the membership affected and the International Executive Board cannot permit District 26 to take ill-considered action by their violating every rule of honorable joint relationship and bring our Union into disrepute.

"The agreement in District 26 was made for a specific period and was ratified by membership of that district by referendum vote. International Executive Board will insist that this contract be continued in force and effect until the specific date of termination.

"It is also true that Article 16, Section 1 of International Constitution prevents your district from engaging in a strike involving all or a majority of its membership without the sanction of the International Union. The International Board does not propose to tolerate any violation of this Section.

"Your statement is in error, when you state your most unwarranted procedure to be in harmony with the policy of the International Union. Your policy is also in error when you undertake to base such action upon statement made in Executive Session by one of the membership of International Commission which recently visited that district.

"This telegram has been sent with approval of International Executive Board and I would like to have official assurances that there will be no violation of the laws and the policy of the United Mine Workers in this respect by District No. 26.

"(Signed) JOHN L. LEWIS."

If District No. 26 persists in taking a strike vote and if it succeeds in causing a strike it is plainly to be seen that its charter will be withdrawn.

While the Convention in New Glasgow was in progress, President Lewis wired instructions that all connection be cut between the Red International and District 26. The District replied that "this had been done; but they reserved the right to do their own thinking." At the same time an extremist labor leader from Sydney was in the Convention and advised the members to "bore from within". This is the communist policy, and who among this element cares what the means are provided the aim is accomplished? It is reasons of the

kind that caused President Lewis to send a commission into the district, and these men have not been slow to interpret the trend of Union affairs in Nova Scotia.

The Steel Strike. — The Sydney public, weary of the long drawn-out labour agitation that has again broken out in violent eruption to the undoing of business, is not sorry that the time has arrived to settle accounts. The long threatened strike began at 3 a.m., on June 28th, when the blast-furnace men and others walked off the plant, but failed to make it one hundred per cent effective. One-third of the men did not respond to the strike call, and it is well known that the majority of the men out on strike are not in sympathy with it. While the labor leaders no doubt intended to have "peaceful picketing," the number of men remaining at work inflamed the more volatile element and considerable rioting took place on the first night. Raid after raid was made on the main plant to intimidate the maintenance men; but these failed, the only men leaving being those who were forcibly carried out. No less than six raids were made on the coke ovens, with the intention of closing them down. It is just such mob action that defeat the aims of the strikers, and destroys whatever sympathy is left for their cause. Whether the strike be long or short, it is quite certain that Sydney Steel Plant, when fully operated again, will have saner workmen, that business will be established on a surer foundation, and that there will be more room for a fraternal feeling among the workmen themselves, and also a better understanding between the officials and the workers.

There is little doubt about the result of the strike. It is the day of reckoning that could not be averted, and must be endured until the test is complete and the cost counted. The workmen of the steel and coal industries of Nova Scotia cannot go on as they have been going, the battle is on, and must be fought to a finish. Labor has long ago discarded conciliation as a worn-out method of settling disputes, and has gone back to the barbarous weapons of warfare. That they will perish by these weapons, is the common opinion of all interested in the strike now going on.

BRITISH COLUMBIA

Kitchener — The Leadville Group of silver-lead claims, near Kitchener, eastern B. C., is under development by Spokane capitalists. A small crew is employed on the property and a road is being constructed to furnish transportation facilities.

Promising Gold Prospect — The Silver Bar Mining & Development Co. Ltd., with holdings near Ewing's Landing on Okanagan Lake, is reported to have uncovered promising showings. There is an ore-body of 36 feet in width which, it is said, have given returns of from $55 to $270 in gold to the ton. A. W. Davis, the Government mining engineer, in his annual report stated that the property was of peculiar interest because of its surface showings. As to mining conditions, two-mile aerial tramway connect the prospect with a dock on the lakside. Timber is plentiful, but water scarce.

Railway Proposed in Portland Canal District — The construction of a railroad from tidewater at Hyder, Alaska, through the Salmon River Valley to the boundary of British Columbia, a distance of thirteen miles, again is being discussed. Chas. F. Caldwell, mining operator, first proposed this work four years ago and organized the Portland Canal Short Line Ry. Nothing was done because the project was considered premature. Now, however, conditions are different. A considerable tonnage of ore, independent of that of the Premier Gold Mining Co., which is handled over its aerial tramway, is promised, in fact, it seems assured. The railway, which is said to offer no unusual or insuperable engineering difficulties, is believed to be a practical enterprise and, from the viewpoint of the mining industry of the district, a necessity. Mr. Caldwell is in London endeavoring to raise funds for the carrying out of the work. A charter was obtained for the railroad some time ago.

A Reprieve for Barkerville — John Hopp, who controls extensive placer holdings in the Cariboo district, will not proceed with the hydraulicking of the ground on which the historic town of Barkerville stands, during this summer. This had been his intention, but a change of plans assures the ancient community at least another year of life undisturbed.

Trail Ore Receipts — A total of 10,870 tons of ore were received at the Trail Smelter, Consolidated Mining & Smelting Co. of Canada, during the week June 8 to 14, the detailed shipments being as follows:

Mine	Tonnage
Alamo, Alamo	94
Bell, Beaverdell	43
Bosun, Silverton	102
Company Mines	9826
Emerald, Salmo	33
Knob Hill, Republic Wn.	54
Lone Pine, Republic Wn.	330
Park Gp., Maryville	30
Providence, Greenwood	4
Quilp, Republic Wn.	103
Salmo Ore., Salmo	41
Silversmith, Sandon	87
Standard, Silverton	156
	10,870

B. R. Mackay in Cariboo — Dr. B. R. Mackay, of Cornwall, Ont., formerly with the Canadian Geological Survey, who accepted a commission in 1920 from Lord Cowdray to make a geological survey of sections in India with particular reference to oil producing possibilities, returned to Canada recently by way of China. Before leaving America Dr. Mackay was engaged in the geological survey of the Cariboo District of British Columbia and he is returning to that field to investigate, on behalf of private interests, the economic possibilities of certain placer gold areas.

Practically the whole of India, Dr. Mackay states, has been covered in late years by geologists and their working parties. He directed operations on the northwest frontier and located some promising structures. He was in the northwest Punjab, in Cashmir, and in Burmah. As a result of his researches one well has been sunk 1,000 feet in the Punjab and something like $1,000,000 is available for the proving of this ground. While there were good formations in the northwest frontier, speaking generally, Dr. Mackay was not optimistic as to the prospects of early development. Conditions were too unsettled. White men were practically unknown in this field and while there he was accompanied by an armed escort and the camps were frequently raided. One of his parties lost two men through such forays. Notwithstanding this handicap, satisfactory progress was made. He, and parties under his direction made geological maps of 3,500 square miles of the northwest frontier, 8,000 square miles of the Punjab, and 5,000 square miles of Burmah.

In Burmah, the chief oil producer of the British Empire, all the producing wells are on one area three quarters of a mile square. On this tract there are 4,000 wells and the derrick structures give the region the appearance of a dense forest. His work was in other parts of Burmah and highly favorable indications were found.

The race for oil, he said, still is a tremendous international competition. In India only British companies could operate, so that Lord Cowdray did not hesitate to invest largely in the development of the field. Upon the results of the test well being sunk in the Punjab depends largely the extent of future development there.

More Ore at Cork-Province — The Cork-Province Mine, Kaslo Creek, is reported to have broken into an important ore-body on the new 400-ft. level. The width is undefined, but on the 300-ft. level the same vein proved to be 300 feet long and from 4 to 30 feet wide. The ore just uncovered is said to be of good milling grade.

Ore Shipments from Mayo — Seventeen carloads of highgrade silver ore from the Mayo Camp, Yukon Territory, are reported at Nena, 215 miles north of Anchorage, Alaska, and at the junction of the Alaska Railroad and the Tanana River. It is valued at $280,000 and was brought by steamer down the Yukon through Dawson and up the Tanana River to Nena. There it is to be loaded on railway cars and shipped to Anchorage whence it will be taken by steamer to refineries in the United States.

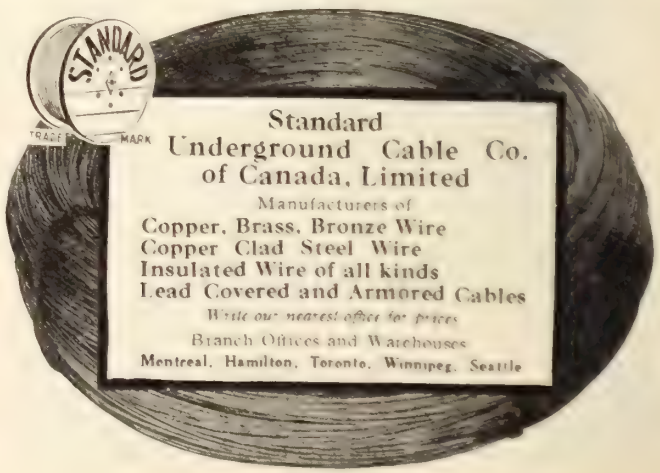
Minister Inspects Mines — Hon. Wm. Sloan, Minister of Mines for British Columbia, has been engaged in making a tour of the underground workings of the coal mines of Vancouver Island. He has been accompanied by the new Chief Inspector of Mines, George Wilkinson. They visited No. 1 and the Reserve, Western Fuel Corporation of Canada, and the Extension, South Wellington, and Nanoose Wellington properties. Next week the intention is to take in the workings of the Cumberland Collieries, Canadian Collieries (D) Ltd. Later on the Nicola-Princeton and Crow's Nest Pass fields will be inspected.

Sulphurous Gases to be Investigated — In making the round of the island coal mines the Hon. Mr. Sloan found conditions as to gas, and in other respects as to the safety of the miners, very satisfactory. Some of the workings places in No. 5 Mine, South Wellington, and the Reserve Mine, near Nanaimo, still are a source of trouble to the miners because of the sulphurous fumes given off by the coal. To this condition the minister paid special attention and he has decided to call in the aid of an eminent bacteriologist and pathologist in order to determine whether something cannot be done to eliminate, or at least alleviate, the trouble. Dr. R. H. Mullin, a recognized authority on health work and industrial hygiene, and head of the Bacteriological and Pathological Department of the University of British Columbia, is to be asked to make this investigation and to submit a report with recommendations as soon as possible.

ALBERTA

Conference on Coal in Winnipeg — It has been announced that Sir Henry Thornton, president of the Canadian National Ry., will attend the conferences to be held at Winnipeg, Manitoba, regardinig freight rates on Alberta coal to Eastern Canadian points. The Canadian Pacific Ry. Co. also will be represented on this occasion and there will be present as well representatives of the Ontario and Alberta Governments, the coal dealers of Ontario and the operators of Alberta. The meeting is expected to take place in the course of a few. weeks. The object is to obtain a rate on Alberta coal that will permit it to be shipped into Ontario and sold at a price that will assure successful competition with imported coals. G. R. Pratt, in charge of the Alberta demonstration office at Winnipeg, states: "We cannot do anything with the $9 rate offered by Sir Henry Thornton and a lower rate is imperative if Alberta coal is to be given a fair chance of competing in the east against American coal. In Toronto hard coal is now being sold at $15.50 a ton. That is a substantial reduction from the prices last winter when it was selling from $18.20 up to $20.50 in Toronto. The prices have come down since we started our eastern campaign."

New Strip Mine to be Opened — An important coal property situated on the south shore of Wabamun Lake, northern Alberta, is being developed by the British Canadian Collieries Ltd. The leased rights obtained from the Canadian Government and the C.P.R. include some 2,200 acres. The coal seam shows on the lake front for the length of a mile and its existence has been known for some time. Development has been retarded because it is on the opposite side of the lake from the railway, making the transportation problem serious. The company has secured a charter for a branch railway eight miles long which will leave the Grand Trunk Pacific three miles west of the town of Duffield and, running southwesterly, will cross the narrows of Goose Quill Bay to reach the mining property. The railway has been surveyed and construction will commence about July 1st next. The coal measures have been thoroughly tested by drill and a seam has been demonstrated 24 feet in thickness throughout. It is estimated that there is 30,000 tons of first class coal to the acre. On 1,200 acres the coal carries an over burden of from 20 to 28 feet. The average depth is 30 feet. It is the intention to strip this, the overburden being removed with a large Bucyrus steam shovel having an 85-foot beam. A smaller shovel will be used to load the coal. First-class screening facilities are to be installed. The heavier machinery will be taken in over the railway as soon as the steel is laid, and it is confidently expected that the industry will be on a producing basis before next winter. Electric power is being provided for all operations.



We Meet Your Specifications

We are prepared to furnish you with a standard line of exact flotation reagents. If you desire, our technical staff will gladly co-operate with you to determine the particular flotation oil which will best meet your requirements.

As soon as the specifications have been established we will guarantee strict adherence to them and practical uniformity in every shipment. We can do this because Hercules Pine Oils are produced under rigid chemical control of every process.

We will supply you with data on any of our flotation reagents and will also advise regarding methods to detect adulteration.

LINDSAY ONTARIO

TO SAVE YOU VALUABLE MINUTES

during the busy hours of the all-too-short business day is the prime purpose of the **ELECTRICAL DIRECTORY OF CANADA.**

Where Can I Buy this electrical fitting or device? You will find the answer in THE ELECTRICAL DIRECTORY OF CANADA. It contains 350 pages and 1200 classified product headings covering the entire field of electrical products used in industry.

Who Is The Sales Manager of Blank & Co., Ltd.? The answer is in a special section of THE ELECTRICAL DIRECTORY OF CANADA. Contains concise information regarding the officers and lines dealt in for upwards of 250 manufacturers and distributors operating in the electrical and power field of the Dominion.

Where Is Blank & Co's Nearest Sales Office? The answer is in THE ELECTRICAL DIRECTORY OF CANADA. It gives the location and street address of each branch and sales office for practically every manufacturing and distributing company serving the electrical and power field in the Dominion.

Who Can Do A Wiring Job For Me In The City of Blank? THE ELECTRICAL DIRECTORY OF CANADA gives the name and address of more than 700 Electrical Contractors and Dealers throughout the Dominion; the favorably known firms in almost every locality of any size in Canada.

Logically Arranged And Adequately Cross-Referenced to make the information it contains readily accessible and to conserve your time.

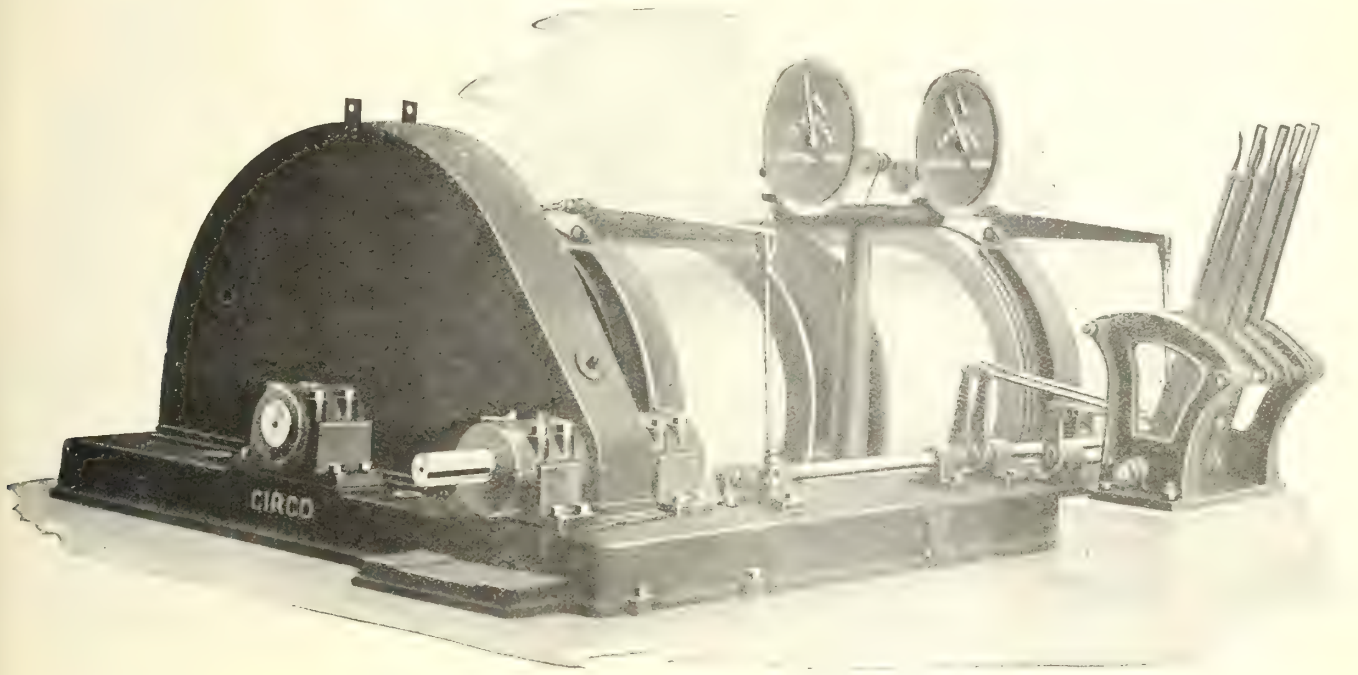
"CIRCO" HOISTS



Your hoist earns every dollar in your treasury

The earnings of your hoist depend on the tonnage it can handle and the tonnage it can handle depends on its power, reliability, and ease of control.

To design and build hoists capable of hoisting or hauling heavy loads continuously at high speeds to meet the requirements of modern mines and collieries calls for wide experience, engineering skill, and exceptional manufacturing facilities.

The size and type of hoist; how to equip it for best results and similar questions are most satisfactorily met by close co-operation on the part of the mine management and the hoist builder.

To the solution of such problems "Ingersoll-Rand" engineers bring the knowledge and experience acquired through more than half a century's association with the mining industry, plus the backing of an excellent manufacturing plant and a highly trained force of skilled mechanics, many of whom have been with the Company for twenty-five years or more.

No matter what the service, size, type of drive or equipment required, you can obtain a "CIRCO" Hoist to suit.

Consult our nearest branch.

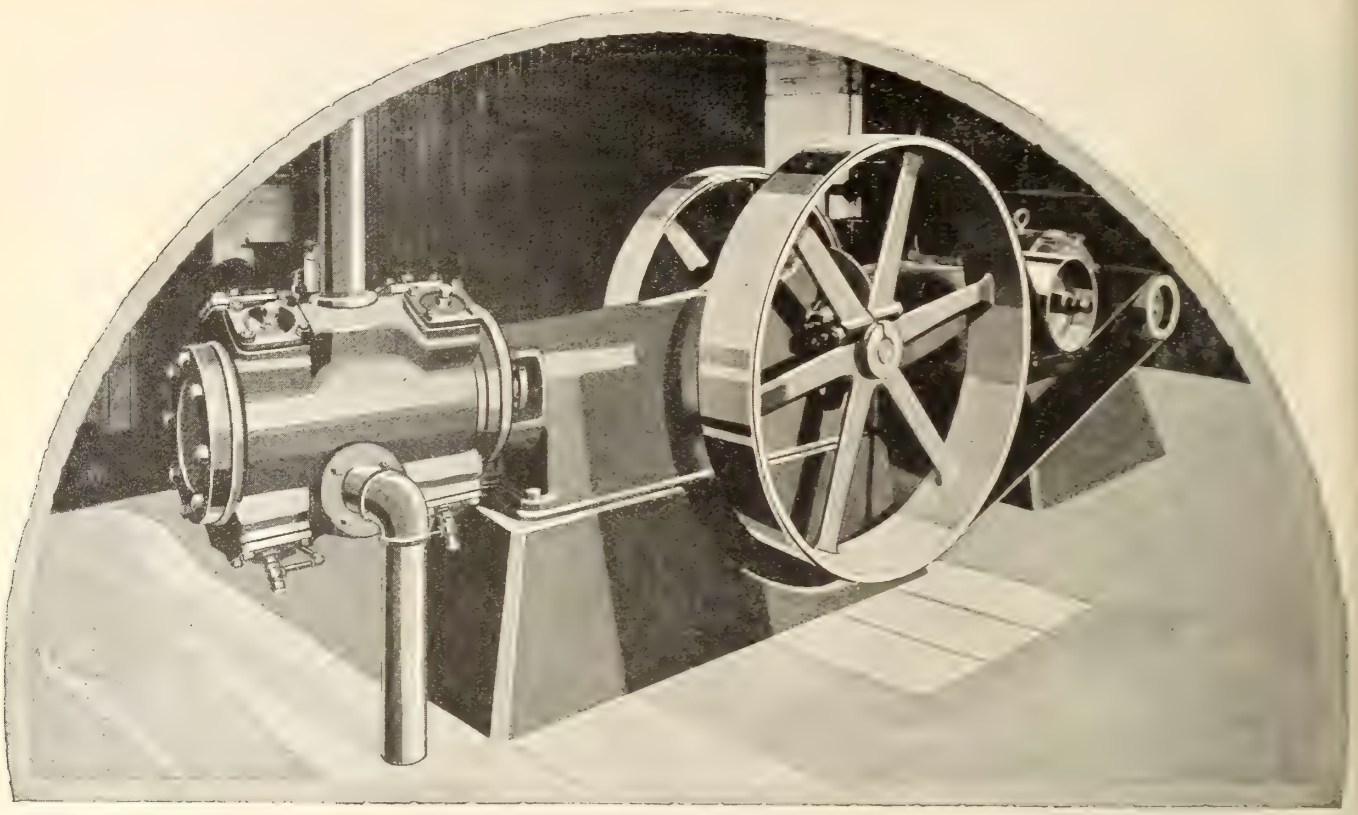
Ingersoll-Rand



The Importance of the Air Compressor

In many operations the Air Compressor is a big factor in operating cost and uninterrupted output. It must be suited to your needs; proper capacity and pressure and the most efficient method of drive.

It must be capable of furnishing compressed air at the lowest cost per cubic foot actual delivery not only when first installed but every hour of its lifetime. This means not only maximum air output for the lowest power input but economical attendance charges and low repair bills.

Class "ER" belt-driven and "FR" steam driven compressors are the choice of operators requiring a machine of small or moderate size. Such features as Ingersoll-Rand Plate Air Valves automatic lubrication and regulation enclosed design, efficient water-jacketing, superior workmanship and high-grade materials insure your getting maximum economy and efficiency.

Class "ER" Compressors are built for either plain or short belt drive. Tight and loose pulleys are also available on the smaller sizes.

Class "FR" Compressors are equipped with a balanced piston steam valve (similar to those used on large locomotives) and automatic cut-off fly-wheel governor.

Write for catalogue K-311, on "ER" or K-312 on "FR" Machines

Private Automatic Exchange

ACTION

The Automatic Telephone

Anything is delay which retards action. Your plant intercommunication may be handled as efficiently as the means permit, and yet delay exists. For there is only one *rapid* means of intercommunication between the widely separated units of a great plant. It is P. A. X.

"A Pair of Wires and a Dial," telling of P. A. X. in operation is yours for the asking. Write our nearest House.

Link-Belt Silent Chain Drives Used Exclusively

at Silver King Coalition Company, Park City, Utah

In rebuilding the mill, after the big fire of the Silver King Coalition Company, the type of power transmission in use was changed completely and Link-Belt Silent Chain Drives were installed *exclusively.*

Now, the Superintendent says: "I will never use any other form of drive but Link-Belt Silent Chain. It is unexcelled in all my experience."

Send for our Data Book No. 125. It is *not* a catalog but rather a handbook on silent chain practice. From it you can figure drives and determine prices. Return the coupon.

Adding Impetus To The Development of Mining

The development of Canada's enormous natural resources will affect her whole future. Her vast mineral wealth, as yet practically untouched, is to-day attracting world-wide interest from far-seeing investors.

It is appropriate that the Imperial Bank, whose policy has ever been to concentrate exclusively on Canadian affairs, should be powerfully furthering that interest. This Bank, by placing branches at strategic points throughout the mining districts, has materially aided the whole industry.

Those who contemplate becoming connected in any capacity with mining would be well advised to take advantage of this Bank's facilities.

THE GOULAIS IRON ORE DEPOSIT

A press report to the effect that a party of prospective investors, accompanied by Mr. J. D. Jones, general manager of the Algoma Steel Corporation, have recently inspected the deposit of iron ore near mile 60 on the Algoma Central Railway, draws attention to the strategic position and potential importance of this deposit. It is a magnetic iron range, a few miles only from the railway, sixty miles north of Sault Ste. Marie. Its future as a possible important producer of iron ore was realized only three years ago, when it was staked and examined in a preliminary way. The first superficial examination has disclosed a vast amount of siliceous magnetite, uniform in quality, free from deleterious impurities, and amenable to modern processes of concentration.

This deposit is in an unusually favourable position to supply the blast-furnaces at Sault Ste. Marie. A single railway haul of sixty miles direct from mine to furnace is much less than the transportation expense to which the present supply of ore is subjected. The necessary investment in a spur line is slight in comparison with the object to be attained. The ore deposit is capable of producing a large annual tonnage for a century or more.

Progress in making use of this Goulais River deposit of magnetite depends essentially upon one factor, the cost of making sintered magnetic concentrate. Should the present large experimental plant at Babbitt, Minnesota, prove to be a commercial success, there is no reason why its success should not be duplicated in Canada. Such a plant in this country would, to be sure, have to be smaller than that contemplated in the United States; but it would be more conveniently located with regard to shipment of ore, and would not require the huge initial investment necessary in the case of the pioneer plant. We are confident, also, that, were a well-rounded and obviously feasible scheme of ore production in Ontario proposed by substantial operators and investors, the Ontario or Dominion Governments, or both, would help to put it into effect by means of a bounty or similar subsidy.

The time is at hand when we can expect some definite and effective action with regard to the production of iron ore in Canada, and particularly in Ontario. Mr. Jones has indicated by practical calculations that the calcined siderite of Michipicoten and sintered magnetic concentrate can be used alone in various proportions to produce whatever variety of iron is required from the blast-furnace. One hundred million tons of siderite at the Helen Mine awaits a plant to turn it into merchantable ore; the process is proved, and there is required only a comparatively slight aid in the way of subsidy to ensure commercial success. If there should be demonstrated during the coming months the fact that the beneficiation of magnetic ore is similarly feasible, then there will be no reason whatever why the taxpayers of Ontario and of Canada should not dip into their pockets to the very slight extent required to establish firmly within our borders the one great basic industry of first-rate national importance for whose support we are at present utterly dependent upon foreign sources of supply.

THE STRIKE AT SYDNEY

The long expected "show-down" has come in Sydney. The workmen of both the steel plant and the collieries have decided to pit their strength and endurance against that of the British Empire Steel Corporation. The officers of the Corporation appear to realize that they can make no concessions, outside of relinquishing their ownership and control of their shareholders' property, that will permanently satisfy the socialist leaders of their workmen. The fact that the public, as represented by police and military forces, have been brought to the scene of the strike in sufficient numbers to protect the threatened plants and mines is sufficient evidence of the Corporation's determination to see this matter through to a finish—at last.

The presence of large military and police forces in and about Sydney points also to another fact — a fact of which the "red" strike leaders are not fully aware. It demonstrates the fact that the Canadian public, through their accredited representatives, are determined that the laws of this land shall be observed, and that the ancient and eminently useful institution of private ownership shall be preserved. In the final analysis it is the rights of private ownership that the strikers have called in question. They may claim that it is other rights of their own for which they are contending; but a careful scrutiny will show that, apart from some comparatively trivial matters, their contentions are based upon the principles of Karl Marx — the principles that rule the Russia of today. During the coal miners' strike of last year, which was terminated by a compromise that indicated a drawn battle and a resumption of hostilities, the same principle was at stake; but it is now

evident that our public representatives were not then so well aware of the fact as they are at present. The case is clearly one of British democracy versus Bolshevism.

At various critical junctures during the last two years of struggle between the workers' leaders and the representatives of investors in Nova Scotia, it has appeared to us unwise to have given rein so freely to the demagogues that at present hold such powerful sway. In one settlement after another the well-organized miners have been conceded the essential point of their demands, with the inevitable result that they have grown to believe they can force almost any concession from the company that pays their wages. Now we see that this policy of drifting along on the basis of a patched-up settlement has more to recommend it than appeared at first sight. It illustrates a propensity peculiar to British democracy — one that has accomplished more in settling acute labour problems in Britain itself than have other methods in any part of the world. The public is the final arbiter of any large-scale labour dispute such as this; and it is necessary, evidently, that the dispute shall have reached a very acute stage before the interest of the public has been roused sufficiently to exercise its judicial function. Sufficient public interest in the present case has now been stimulated, we take it, to ensure a permanent and judicial settlement.

* * *

Meantime events in the industrial area of Cape Breton have moved rapidly. The steel strike has collapsed and the furnaces and mills are at work again, due fundamentally to the fact that one-third of the employees remained at work. The plant has been idle or running at reduced capacity for so long that most of these men are on the verge of destitution and can ill afford a strike, however, just the cause. In this case the cause is of doubtful merit, and the spectre of hunger has proved a more potent persuader than the arguments of radical leaders.

The arrest of McLachlan and Livingstone is long over-due. At last, however, their published libel on the provincial police has proved their undoing. It is a well recognized fact in Sydney that most of the talk of these and other radical labour leaders has been a fabric of lies, and even their dupes among the rank and file of the miners' union are beginning to realize this fact. When the whole truth is made known to the misguided miners, we shall see the "red" leaders, elected with such demonstration last year, deposed and the more moderate leaders re-installed in control.

John L. Lewis has sent a definite order to the U. M. W. A. executive in Nova Scotia to call off the strike and return to work. A refusal on the part of the District executive will involve their being outlawed by the International union. If this should happen, the miners will be brought safely back to the U. M. W. A. fold the quicker; for the demonstrated faithlessness of the Nova Scotia "reds" means that ostensible submission would signify merely a continuance of plotting against the headquarters at Indianapolis.

Precipitate and ill-advised action on the advice of extremist leaders has led the workmen of Cape Breton into a situation from which they cannot escape. The steel workers have submitted to the inevitable with sufficient grace to ensure them generous treatment from the British Empire Steel Corporation. The miners, longer supplied with the intoxicating liquors of Bolshevism, have committed themselves more deeply and with less reason than their fellow-workers. They can expect sterner justice from the national and provincial governments whom they have defied and from the company whose property they have sought to destroy.

FREIGHT RATE ON ALBERTA COAL REQUIRES INDEPENDENT INVESTIGATION

Today we print, on another page, an official resumé of the interim report of the Dominion Fuel Board. As we have noted before in these columns, this excellent report deals fully and fairly with the various phases of the problem, with the exception of the transportation to Ontario of Alberta coal. A solution of this phase of the problem would put in sight complete fuel independence for this country. A solution is, however, not yet in sight.

The report of the Dominion Fuel Board did not discuss the question of freight rates on Alberta coal. The only really definite evidence available is that from the traffic departments of our two railway systems, who agree that the cost of hauling the coal to Ontario would be about $9.00 a ton, a prohibitive rate. Accepting this evidence as final, one must conclude that the only hope of getting Alberta coal into Ontario is by means of a subsidy that will reduce the freight rate. Such a subsidy would involve political policy and an Act of Parliament, and thus would be beyond the scope of the Dominion Fuel Board. It is this conclusion, presumably, that has led the Board to omit from its report discussion of this all-important topic.

The House of Commons Committee on Mines and Minerals, representing a political body, has not found itself under the same stricture as the Dominion Fuel Board. In its final report on June 27th, after hearing a great deal of evidence on the fuel question, it made the following recommendation to Parliament: "Your "Committee further recommends that the Govern- "ment undertake an independent investigation imme "diately, through whatever channels it deems best, "to ascertain the actual cost of carrying coal from "eastern and western points to Central Canada. We "believe that our National Railway should carry fuel "at cost in this crisis, and your Committee suggests

" that the rates quoted are not cost rates but much " higher." Western Canada was strongly represented on this Committee, so it may be that their conclusion is directed more by hope than by unbiased judgment.

Meantime, so far as the public are concerned, the point remains unsettled The railway operators say $9.00 is the cost of hauling the coal. Some other transportation specialists say that, by means of using the proper facilities, a much lower cost price can be attained. As the House of Commons Committee pertinently remarks, the importance of the conclusion involved, upon which hinges virtually the supply of a large part of Ontario's coal supply from Canadian mines, warrants the expense of an independent and thorough investigation.

INVESTIGATION OF DOMESTIC COKE MANUFACTURE

A second important item in our fuel problem is the conversion of bituminous coal into a high-grade domestic fuel-coke. The conclusion on this point is clear; it can and will be done. Early last spring the British Empire Steel Corporation undertook to investigate the point for themselves, and engaged the services of the Koppers Company for this purpose. The result is set forth in a letter from Mr. R. M. Wolvin, President of the British Empire Steel Corporation, to Senator McLennan, chairman of the Senate's Fuel Committee. In this letter he states that it is entirely feasible to transport Nova Scotia coal to such centres as Montreal, Quebec and Toronto and there turn it into coke, and to clean the gas for domestic or industrial use. He suggests trans-shipping coal at Montreal from seagoing colliers to the canal-size boats that otherwise would return empty to Port Colborne. Mr. Wolvin's conclusion would have borne more weight had he not added that "it will be necessary for the Canadian Gov- " ernment to assist this new business by bonus on coke " produced from Canadian coal or by subsidising such " plants using Canadian coal in a way possibly similar " to the Dry Dock Subsidies."

The Dominion Fuel Board have arrived at the same conclusion with regard to the provision of domestic coke, and in their interim report stress this as the main issue in the "acute fuel area." They do not count upon the exclusive use of Canadian bituminous coal for this purpose, as that would, no doubt, depend upon such a subsidy as Mr. Wolvin suggests throughout the central and western parts of Ontario. Their interim report points out that, whatever the source of this bituminous coal, it is desirable to turn it into its derivatives, coke, gas, ammonium sulphate and minor by-products, in place of using it in the raw state. To arrive at a sound conclusion on this point they engaged the services, last spring, of authorities in the United States who have investigated this selfsame question in various centres of population in that country. A survey of certain Canadian centres has led to the conclusion stated in brief in the interim report. The survey is in progress in other centres, and when the Board issues its final report we can be confident that its conclusions with regard to the manufacture of domestic coke will be as complete and as authoritative as it is possible to have at this time. It should be noted, by the way, that this preliminary report has been issued with unusual expedition after the appointment of the Board. The secret of this speed is probably to be found in the fact that it has consistently taken advantage of the knowledge of the best constituted authorities, rather than make independent investigations, which might consume years to gain the same end. Thus, whatever the success of Alberta coal in Ontario, the urban communities in eastern Canada with a population of 100,000 or over can look forward confidently to being supplied soon with high-grade fuel and cheap gas, and the surrounding agricultural districts to an abundant supply of fertilizer, all from bituminous coal.

A research association for the advancement of their trade, is the aim of the clothing designers of Canada and the United States. This is the gist of a report emanating from their annual convention held in Toronto last week. So it looks much as if Canada's clothing designers, by virtue of their association with their fellows in the United States, where research is the vogue in industrial circles, were to be the first in this country to benefit from this modern aid to progress. Apparently the mining, iron and steel, chemical, metallurgical, and all our other industries can afford still to rely upon individual effort. We doubt that their conclusion is sound.

ROUYN, OR WHAT'S IN A NAME?

Where wolverines their greed assuage,
  Where gambols portly Bruin,
Where moose live to a goodly age,—
  (The place I mean is "Ruin")—
Where there is neither shop nor house,
  Where one can't get Chop Suey,—
That hash of cabbage, cat, and mouse,—
  (I now refer to "Rouee")—
Where white the moon smiles down on men,
  The silvern, northern moon,—
(Where time and time and time again
  One hears the name called "Roon",)—
'Tis there, 'tis there, that I would be,
  Far, far from human clatter:
(And not one tinker's dam to me
  Pronunciations matter.)

J. C. M.

The Collieries of British Columbia

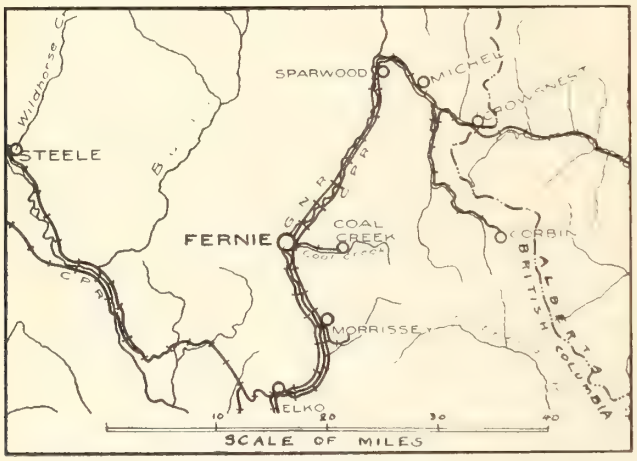
I — The Crow's Nest Pass Coal Field

By ROBERT DUNN

Of the coalfields of British Columbia in which there is active mining the most important is that of the Crow's Nest Pass, situated immediately west of the summit of the Rocky Mountains. The accompanying sketch indicates the chief mining centres of the district. The area of Cretaceous rock in this vicinity is nearly 500 square miles in extent. In relation to the remainder of the Province this field may be said to be located practically on the eastern boundary, between British Columbia and Alberta, and in the extreme eastern part of the Kootenays.

First Colliery Established in 1900

No. serious exploitation of the measures took place until the year 1900, the Crow's Nest Pass Coal Company having been floated shortly before that time. Since then the industry has been well maintained and, while it cannot be said to have grown in marked degree during the past few years, the collieries of the Crow's Nest



Sketch Map to show Location of Mines in Crow's Nest Pass Coal Field

have been one of the outstanding factors in western industrial progress. Up to the year 1908 the Crow's Nest Coal Company was the only company actually producing coal. In that year the Hosmer Mines Ltd. and the Corbin Coal & Coke Co. Ltd. were launched. The Hosmer Company closed down operations in 1914 and the plant has been idle ever since. The reason given for this was bad overhead conditions in the mine, the pressure being so great, it is stated, that it was found impracticable to proceed with underground development.

The original company, Crow's Nest Pass Coal Company, has operated without cessation ever since becoming established. This is not to say that the enterprise has been without its vicissitudes, for work has been interfered with over considerable periods by strikes, accidents and like occurrences; but on the whole, coal has been mined steadily over the period named. The Corbin Coal & Coke Company also has operated continuously since 1908. These two companies have produced from their various mines up to the present 4,887,196 tons of coal and 759,393 tons of coke.

Geology of the Area

Mr. James McEvoy, in a report for the Canadian Geological Survey in 1900, states that the coal-bearing horizon of the Crow's Nest coalfield is what is known as the Kootenay formation, and occurs in synclinal form covering an area of 230 square miles, surrounded by tilted beds of earlier geological periods. As a result of erosion the Kootenay and overlying strata form an elevated plateau-like area bordered by depressions occupied by older beds. He continues:

"Most of the heavy coal seams occur in the lower 2,000 feet of the Kootenay. On Sparwood ridge, near Michel, a further thickness of 2,000 feet in the upper part of the measures contains a number of thin seams, mostly cannel or coal having a high percentage of volatile matter. The Morrissey section at the south gives a thickness of 3,700 feet of coal-bearing beds. The covering beds are mostly coarse sandstones and conglomerates and are of great thickness.

"The coal content, in natural sections at a number of places, including only seams over one foot in thickness, is as follows:— At Morrissey 23 seams give 216 feet of coal in 3,676 feet of measures. At Fernie 23 seams give 172 feet of coal in 2,250 feet of measures. At Sparwood 23 seams give 173 feet of coal in 2,050 feet of lower measures. At Sparwood 24 seams give 43 feet of coal in 2,015 feet of upper measures."

The Pioneers

Two names are prominently associated with the early history of coal mining in the Crow's Nest. One is Lt. Col. James Baker, who was Minister of Mines and Education and Provincial Secretary in the administrations of Theodore Davie and J. H. Turner and who came to British Columbia in 1884. The other is William Fernie, a prospector, who had discovered and been impressed by the coal riches of the district and who was responsible for inspiring Col. Baker with his enthusiasm. Both these pioneers have passed to their reward, the first mentioned retiring to England after having seen his enterprises successfully brought to fruition, and the latter ending his days in Victoria, confortably sustained by the yield of his energy and business acumen.

It was in 1887 that Mr. Fernie told Col. Baker of his discovery of a 14-foot seam of coal while engaged in cutting a trail through the Crow's Nest Pass. To recount in detail all that grew out of that conversation would take considerable space and possibly would bore the reader. In brief, a syndicate was formed; the area was well explored and many other promising outcrops were located; approximately 11,000 acres of land was purchased at $1 an acre; and then Col. Baker tackled a very serious phase of his problem, viz. the provision of transportation.

There was no doubt as to the existence of the coal; nor was there any doubt regarding its quality; but it must be remembered that in these early days in this part of the country the means of carrying the commodity to market were lacking. The difficulty then confronting the Crow's Nest Pass was analogous to the difficulty that now is being met with by those who would exploit the coal measures of the Ground Hog district in the far northern part of British Columbia. The presence of large coal seams had been proven; how could the product be brought to the consumer at a profit?

Railways Built by C. P. R.

Two companies were formed in 1888, one the Crow's Nest Pass Railway Co. and the other the Crow's Nest Coal Co., the latter holding the 11,000 acres of coal land. A railway charter was granted by the Provincial Legislature. Nothing, however, was done immediately, and in 1890 the British Columbia Legislature passed the "Railway Aid Bill" under the terms of which a grant of 20,000 acres per mile of railway constructed was offered in order to encourage the building of a railway that would tap the district by way of the Pass. Every possible effort was made to induce eastern financial men to take up this offer. These endeavors, however, were unsuccessful and finally the Canadian Pacific Railway agreed to construct the road providing a subsidy was granted by the Dominion Government. The agreement of the C. P. R. provided that that Company was to pay $100,000 for the provincial railway charter, that this sum was to form working capital for the development of the coal mines, and that they were to hand over the coal lands attaching to the railway land grant and amounting approximately to 170,000 acres, besides a block of land of about 400,000 acres useful, it is stated, only for timber for the mines. The C. P. R. retained 6,000 acres of the best coal land on condition that they should not work the same so long as the coal company provided coal at a profit not exceeding 75c a ton. The C. P. R. was granted a subsidy by the Dominion of $11,000 per mile, but the Dominion held 50,000 acres of land, the coal content of which was not to be exploited providing cheap coal was sold by the company.

This, then, was the genesis of coal mining in the Crow's Nest. Anyone who has been through that country is aware of the remarkable changes that have since taken place. The hub of the industrial area is Fernie, a thriving community on the banks of the Elk River and in daily communication by railway with the southern cities of Alberta to the east and the substantial city of Spokane, Washington State, to the south. Surely the conditions have radically altered since the summer of 1887 when Col.Baker and William Fernie first discussed the development of the coal of the region, and no doubt had clear visions of what the future might be expected to bring forth under the compelling force of industry. Col. Baker was an English gentleman with little idea of western Canadian life when first he arrived in this country. His first intention was to go ranching, and to carry out that purpose he purchased a large tract of land some distance south of the Crow's Nest, a part of which now is the site of Cranbrook. It was not long before he was drawn into the vortex of western life, and we find him not only taking a firm grip of the problem of coal development, but also a very active and leading part in the public life of the Province.

Crow's Nest Pass Coal Co.

At the head of the Crow's Nest Pass Coal Co. is W. R. Wilson, who for years has been associated with the company, first as General Manager and later as President. The Company is operating the Coal Creek Colliery, on Coal Creek, about 5 miles from Fernie, and the Michel Colliery, on Michel Creek, about 23 miles northeast of Fernie.

Coal Creek Colliery of the Crow's Nest Pass Coal Company

In connection with the Coal Creek operations there are seven mines, three on the north side and four on the south of the creek. The Morrissey Fernie & Michel Railway gives Fernie connection both with the Canadian Pacific and the great Northern Railways. Coal trains are run over a short line from Fernie to Coal Creek and in addition a regular passenger service is maintained for the convenience of workmen, most of whom live in Fernie. Dwellings, however, are provided at Coal Creek for those who prefer to live near the mines.

Method of Mining

The seven mines referred to are Nos. 1 East, 1 South, 1 North; Nos. 2, 3, 9 and B North. No. 1 Mine operate in No. 1 Seam, which varies from 30 to 40 ft. in thickness, only 10 ft. of the upper portion being worked. Nos. 2, 3 and 9 mines are mining the No. 2 seam which has an average height of from 6 to 9 feet; while B North is working the B seam which is about 5 ft. thick, height being obtained for haulage by lifting from 3 to 4 ft. of bottom, this consisting chiefly of inferior coal and shale. The general method of work is pillar and stall, entries being driven in pairs, from which rooms are set off three to a panel, large pillars being left between each pair of entries and set of rooms. All the coal is

mined from the solid, no pillars having been drawn. Inside the mines the haulage is by horses from the working faces to convenient partings, from which the loaded cars are conveyed to the tipple by low pressure, compressed air hoist, compressed air locomotives, endless rope haulage, and gravity planes. The Edison type electric cap safety lamp is in general use, although there are Wolf safety lamps for officials and brattice men for testing purposes. The tipple at this colliery is of steel construction, has a total length of 840 feet, extending right across the valley, and receives coal on both sides; it is equipped with two independent electrically driven circular dumps, which deliver the coal to feed-conveyors that supply the shaking screens. These separate the slack from the lump coal, the latter being delivered to the picking-tables, where all foreign material is picked out before it is finally loaded into the railway-cars.

Provision is made for loading into either open or box cars, two Smith hydraulic box-car loaders being provided for dealing with the latter.

Equipment at Central Plant

The main power plant is situated on the north side of the valley and consists of fourteen boilers, with an auxiliary plant of five boilers on the south side; the total capacity of the plant is approximately 3,250 horse-power. Power to drive the compressed-air hoists and pumps underground is supplied by three compressors having a total capacity of 6,000 cubic feet of free air a minute, compressing it to 80 lb. to the square inch. There is also a Canadian Ingersoll-Rand (high-pressure) compressor having a total capacity of 1,346 cubic feet of free air a minute, compressing it to 900 lb. to the square inch, which provides the power to drive the air-locomotives.

The electric plant consists of three generators with a capacity of 680 amperes at 250 volts, driven by two Robb-Armstrong engines, and provides the power to drive the fans at Nos. 1 South, 1 North, and B North mines, the motors on the tipple, as well as the electric light for the mine buildings, yards, and houses at Coal Creek.

A well-equipped lamp-room is located in a central position at the mines, where all safety-lamps are cleaned and repaired; this building is fully provided with all necessary appliances for keeping the lamps in a good state of repair. A large wash and change room is situated convenient to the mines, where the workmen can have a locker for a small monthly payment; these lockers are of steel construction, and the wash-house is under the charge of a workman whose duty it is to keep it in a clean and sanitary condition, the workmen providing their own soap and towel.

Descriptions of Separate Mines

No. 1 Mine is opened by a crosscut tunnel, which reaches the coal at a distance of 215 ft. from the entrance. A fan of the Wilson type provides ventilation, running at a speed of 146 revolutions a minute and delivering an average of 116,500 cubic feet of air per minute at a water gauge pressure of 3.5 inches. There are four splits in the mine and ventilation is good. Coal dust is kept down by spraying all roads and all working places where it is necessary. The main roads are regularly treated with ashes. John Caufield is the overman.

On the eastern and dip portion of the No. 2 seam is the No. 3 Mine, J. Biggs, overman. The coal is reached by a slope 2,500 feet in length from which the product is delivered direct to the tipple. Ventilation is furnished by a 16 x 8 ft. Wilson fan delivering some 55,900 cubic ft. of air per minute. A spraying system has also been adopted in this mine.

The western portion of No. 2 seam is opened up by No. 2 Mine, C. McNay, overman. This is on the same level as the tipple, to which loaded cars are delivered direct by compressed air locomotives. A Wilson fan delivers about 48,200 cubic feet of air a minute. The ventilation is split for two separate districts.

About half a mile to the west of the tipple and operating on the upper and western portion of No. 1 seam on the south side of the valley is No. 1 South Mine. All workings are to the rise of the main haulage road and driven toward the outcrop. An electrically driven 8 x 4 ft. Keith fan provides ventilation. It gives some 36, 360 cubic feet of air a minute. F. Landers is the overman.

No. 1 North Mine is operated on the western portion of the No. 1 seam on the north side of the valley and being close to the outcrop little trouble is experienced from gas. It is all on one split and ventilated by an electrically driven 7 x 4 ft. Keith fan producing an average quantity of 23,000 cubic feet of air a minute. J. Worthington is the overman.

The No. 2 seam on the north side of the valley is opened up by No. 9 mine, R. Fowler in charge. The principal recent work has consisted of driving two companion inclines with the intention of making connection with No. 1 North Mine and repairing the main return airway. A Guibal type fan giving some 7,400 cubic ft. of air a minute provides ventilation.

East of the tipple is No. B. North Mine, which is opened on the B seam. W. Commons is the overman. An electrically driven 10 x 3 ft. Brazil fan producing about 41,800 cubic feet of air a minute takes care of ventilation.

To be continued

PERSONAL AND GENERAL

Mr. A. S. McNeil, formerly General Superintendent of the Dominion Coal Company, has been appointed Assistant General Manager in place of Mr. H. J. McCann, who is seriously ill.

Mr. John Blizard, formerly on the staff on the Mines Branch, Ottawa, has resigned his position as fuel technologist with the Bureau of Mines, Washington, to take a post with a private company in New York.

Dr. Robert Harvie is engaged for the field season in mapping that section of the Rouyn gold field of northwestern Quebec lying to the north and east of Rouyn township. Other members of the Geological Survey are engaged in mapping the other map sheets covering the gold belt.

Colonel Crabbs, President of the Granby Company, on his recent visit to the Company's mines and plant at Anyox, B. C., took occasion to compliment those responsible for the community life of this little town. It is notoriously difficult to manage the affairs of a small and isolated community like this in such a way as to minimise personal friction and to stimulate a normal and sound outlook on life. Colonel Crabbs has corroborated the expressed opinion of other observers, that the spirit of good fellowship as well as of loyalty to the Company has reached a remarkable state of development in Anyox.

The world's present radium consumption is about 2 grams per annum. This supply can be more than met from the plant for the treatment of the rich Katanga radium ore at Oolen, near Antwerp, Belgium.

The Phospho-Potash Process

Method of Treating Potash Feldspar Worked out by F. D. S. ROBERTSON

Efforts are being made continuously to develop a commercially feasible process for extracting potash from feldspar. Eventually some such process is certain to be evolved. Canada is particularly favoured with deposits of potash feldspar of large size in easily accessible localities, and has at present no available source of potash. Consequently a solution of the problem is of decided importance to this country.

A method called the "Phospho-Potash Process" has been worked out recently in laboratory and small-scale experiments by Mr. F. D. S. Robertson, Metallurgist of Toronto, and patented. (Canadian Patent No. 191,260, July 1st, 1919, and U. S. patent No. 1,317,524, Sept. 30, 1919.) It consists essentially in the treatment of ground potash feldspar with phosphoric acid. The phosphoric acid attacks the silicate of potash and alumina, giving potassium phosphate, alumina and silica, the first being thereafter leached out with water. The alumina and silica are removed by filtering, and the solution of potassium phosphate is treated with sulphuric acid to give potassium sulphate and phosphoric acid. By evaporation the potassium sulphate is crystallized and separated, leaving the syrupy phosphoric acid ready to treat a further batch of feldspar. Thus, the products are pure potassium sulphate and a mixture of alumina and silica. This mixture can be separated readily into its component parts, alumia, which is readily saleable, and silica, which will have at least the value of fine silica sand. If advisable, the alumina can be treated with sulphuric acid to make alum, and the silica separated at the same time.

Laboratory Tests

The first tests in the series of experiments were made in the laboratories of the University of Toronto. A quantity of feldspar and apatite were obtained from deposits in Eastern Ontario and were ground to about 80 mesh. From the apatite phosphoric acid was made, and the feldspar was treated with this, as well as with pure phosphoric acid purchased. The initial tests were necessarily only on a laboratory scale and were made to ascertain the action of the acid upon the silicate and the feasibility of recovering the phosphoric acid for use again on fresh material. The result of these experiments es tablished the fact that phosphoric acid, under proper con ditions, attacks feldspar and other silicates and that under the right conditions, ninety-five per cent. or better extraction of the potash content is possible, and that the phosphoric acid could be used over again practically without loss.

Small Commercial Scale Researches

To determine the best conditions under which a satisfactory extraction could be made, a small plant was erected at Guelph, Ont., which consisted of a 75-gallon autoclave or digester fitted with a stirring device driven by an electric motor, large leaching vats, a wooden filter press (Shriver type), a series of open tanks (lead lined) for evaporating solutions and preparing phosphoric acid from the phosphate rock, pumps for transferring liquids, crusher and screens for reducing the materials. A small but complete chemical laboratoy for making control tests was installed. Several tons of feldspar was crushed to 80-100 mesh and also some high-grade rock phosphate. From the latter material a quantity of 47 to 50% acid was made and was used in the trials. It was soon found that, by using an excess of phosphoric acid, all of which is recovered and remains within the circuit, an extraction of at least ninety-five per cent of the potash content of the feldspar was readily effected. From the last four batches extractions varying from ninety-seven to almost one hundred per cent.. and averaging slightly over ninety-nine per cent. were made. The loss of phosphoric acid (which in the cases quoted all went into the sulphate of potash) did not exceed three per cent, and this was found recoverable, if required, by recrystallization. The various salts obtained from these operations were of a high degree of purity.

The process patents cover the treatment of feldspar, mine tailings or other source of potash-bearing material either by digestion under pressure in autoclaves (pressure digestion tanks) or by incipient fusion in furnaces provided with fume collectors. Though feldspar is the chief potash-bearing mineral in Canada, there are a number of other minerals of common occurrence in other countries that will probably be amenable to treatment by this new process. Glauconite (greensand), alunite, and sericite (potash mica), syenite and certain mine tailings are also suggested as possible sources of potash by this method.

The "Phospho-Potash Process" requires only cheap and easily obtained raw materials. The most expensive reagent, phosphoric acid, is regenerated and used over and over again. The only other reagent, sulphuric acid, is recovered completely as the sulphates of potassium and aluminium. Should commercial application prove that the process is economically as well as technically feasible, it will be of decided importance to the Canadian mineral industry.

NEW MAP OF MICHIPICOTEN DISTRICT

The Geological Survey, Ottawa, has issued a new map on a scale of a mile to the inch of the Michipicoten District, to the northeast of Lake Superior, which will accompany a memoir by W. H. Collins, now in course of preparation. Pending the publication of the report, the map will prove very useful.

The map-sheet includes the ground west of the Algoma Central railway for a distance of 20 miles, and from Michipicoten River northward for a distance of 25 miles, or within five miles of the Canadian Pacific Railway. It thus covers the huge siderite deposit at Helen Mine, the lesser siderite deposits in other iron ranges in the vicinity, the old gold camp in the vicinity of Michipicoten Harbour, and the western part of the new Goudreau gold camp.

This is the first official map of this important mineral district to be issued since 1905, when the Ontario Bureau of Mines had the area surveyed. Since that time the science of geology has made great strides, which are well indicated on the new map.

The "iron formation," which is such an outstanding geological feature of this district, has up to the present remained rather an engima to geologists, and especially so the huge lenses of siderite associated with the thin iron oxide and silica bands in this locality. Dr. Collins has made a special study of these deposits and no doubt his memoir will throw some light on the subject.

Field Work of the Geological Survey

By W. H. COLLINS, Director.

The Federal Department of Mines has had prepared by the Director of each of its three branches a statement of the present year's work in field and laboratory. That of Dr. Collins, for the Geological Survey, follows, and those of the Mines Branch and the Victoria Memorial Museum will appear in succeeding issues. — Ed.

Forty-eight parties have been placed in the field in various parts of Canada this summer by the Geological Survey, as compared with thirty-nine parties last year. The most northerly party is working in the Mackenzie river region, in latitude 65 deg. The westernmost one is located in Yukon territory and the easternmost in Nova Scotia. One of the principal objects of the work is to render scientific guidance to prospectors and explorers in their search for mineral deposits by providing them with dependable maps that show the geographical features and the distribution of the various rock formations, and with reports describing the mineral-bearing possibilities of these formations. Several of the parties are more particularly engaged in making inventories of Canada's resources of iron ore, petroleum, coal and other minerals. Nearly all, and more especially the topographical parties, are contributing to the exact, primary mapping of the country on scales suitable to future as well as present needs. This work, although restricted to mineral-bearing areas in which there is a present economic need for good maps, is being carried out with a view to serving all other needs and of forming part of the primary system of maps which Canada in common with all other civilized and industrialized countries eventually should have.

Concurrently with the examination of mineral deposits and the exploration of northern Canada, an opportunity is afforded to most of the parties to carry on the more purely scientific investigations which each year help to transform the exploration of our mineral resources from a haphazard search to one guided by definite principles such as the well informed agriculturist, for instance, already employs. It is a knowledge of such principles already determined which has in Sudbury district, Ontario, for example, confined the search for nickel-copper ore with extraordinary success to the edge of the body of igneous rock which gave off this ore, and in the same district has discouraged and prevented a fruitless and wasteful search for coal. A more recent practical application of geological principles is being made in northwestern Quebec, where the knowledge of the origin and geological relationships of gold-bearing veins learned in the adjoining region of northern Ontario is being applied with promising results by geologist and prospector. The field work of 1923 will afford numerous opportunities for scientific investigation of this nature.

The field work of the Geological Survey affords a good opportunity to students of geology in Canadian universities to make practical application of the information imparted to them in these institutions of learning. This year 77 students in geology and mining or civil engineering are being employed as field assistants. Ten of these are post-graduate students in Canadian and United States universities, to each of whom has been assigned a problem for research which will be initiated in the field during the summer and completed next winter under the supervision of the universities. This arrangement is as advantageous to the Survey as to the universities, for it secures exceptionally intelligent and willing assistance at no greater cost than ordinary labor.

Two of the 48 field parties are engaged in collecting mineral specimens and fossil remains for the national Victoria Memorial Museum, at Ottawa.

British Columbia and Yukon

W. E. Cockfield will investigate the rich silver-lead ore-deposits near Mayo, Yukon Territory, and the country around Beaver river, where discoveries of similar deposits have recently been made.

With the assistance of A. H. Bell he will also continue the geological mapping of an area of 5,000 square miles around Whitehorse which lies on the eastern edge of the Coast granite. This granite intrusion has been responsible for most of the metallic mineral deposits in western British Columbia and Yukon, and the territory marginal to it is particularly worthy of the prospector's attention. Deposits carrying copper, gold and silver have already been found in the section of the eastern margin near Whitehorse.

George Hanson will explore another section of the eastern margin of the Coast granite mass in British Columbia between the Canadian National railway and Portland Canal District, where the Premier gold mine and Anyox copper mine are located. This is in continuation of work commenced in 1922.

W. H. Miller will make surveys for a contoured topographical map, on a scale of one mile to the inch, of an area of about 200 square miles east of Hazelton and northwest of Smithers, on the Canadian National railway. This area contains promising deposits of copper ore and will be geologically mapped after the necessary topographic base-map has been prepared.

G. A. Young will continue a detailed investigation and inventory, begun last year in co-operation with the Department of Mines of British Columbia, of the iron ore resources of the province. It is proposed to study and inventory the iron ore deposits in a manner which will admit of determining whether there are enough ores suitably located and of satisfactory qualities to supply a future iron and steel industry on the coast, if other essential requirements for such an industry obtain. The possibility of establishing a Coast iron and steel industry has been under consideration at various times in recent years and a distinct need has arisen for reasonably accurate information regarding the basic requirements.

T. B. Williams will complete the detailed mapping and study of the structure and succession of strata in the Nanaimo coal basin, on the east side of Vancouver island. This field work was commenced in 1921 and concluded last year by the late J. D. Mackenzie, but his untimely death in December, 1922, prevented completion of his results for publication, and necessitated continuance of the work by Mr. Williams. The coal measures in Vancouver island are complicated by minor faulting and by the irregularity of the floor upon which they were laid down and a careful determination of the geological structure is required for the economical direction of mining operations. An estimate has also been made of the supplies of coal in the basin, as a contribution to the general inventory of the coal resources of Canada.

W. A. Johnston will continue the investigation and geological mapping of the gold-bearing placers and other

loose deposits near Barkerville and Cedar Creek, in the Cariboo district. Interest in the Cariboo placers which were discovered over 60 years ago has been quickened by the discovery last year of a rich section at Cedar Creek. The placers are mostly in gravels of an ancient drainage system of Tertiary age which has been replaced by a new stream system since the Ice age and concealed by the cover of boulder-clay left by the ice-sheet. An interpretation of this ancient drainage is therefore required for the rational prospecting of the placers. With this object in view a topographic map has been made of an area of about 200 square miles around Barkerville. Last year the bedrock formations in this area were mapped and the source of the placer gold investigated by W. L. Uglow, while Mr. Johnston commenced the mapping and study of the placers and other surface deposits which he will complete this summer.

C. E. Cairnes will continue a geological exploration of an area in southwestern British Columbia southwestward from Princeton, in which a variety of mineral deposits are known to occur.

V. Dolmage will make an intensive investigation of the Copper Mountain group of copper ore-deposits near Princeton. A detailed topographical map of the area on 1,000 feet to the inch was made last year by D. A. Nichols.

A. C. T. Sheppard will at the request of the Government of British Columbia make surveys for a detailed topographical map of Kokanee Glacier park, near Nelson. The surveys will also be extended to those already made of the Slocan and Ainsworth areas and will be a further contribution to the standard primary mapping of British Columbia, on the scale of one mile to the inch.

M. F. Bancroft and *J. F. Walker* will continue the systematic geological mapping of Windermere map-area. This work is part of a scheme of geological work which is aimed to correlate and unify the many isolated pieces of geological work in southern British Columbia and permit the compilation of one general geological map of this region. The Windermere area also contains deposits of gold.

Northwest Territories

G. S. Hume will complete a systematic geological exploration and investigation of the petroleum-bearing possibilities of the country accessible from Mackenzie river, which was commenced in 1921. The area to be explored this year lies just south of Fort Norman, where petroleum was found in 1920 and where further drilling operations will be carried on this year by the Imperial Oil Company. When this area has been finished fairly detailed information and maps will be available regarding all the navigable tributaries of the Mackenzie between Great Slave lake and Carcajou river and of the geology and general character of this stretch of country.

Dr. Hume will also investigate and sample deposits of clay, reported to be of good quality, which outcrop on Athabaska river below Fort McMurray.

Alberta

J. R. Marshall will continue the systematic geological mapping of the coal-bearing area in the eastern Rocky Mountains in the neighborhood of Kananaskis river. This work is contributory to a systematic investigation of the structure and distribution of the coal measures and an inventory of the coal resources of Alberta.

P. S. Warren will, at the request of the Parks Branch, Department of the Interior, study and map in detail the rock formations near Banff, more particularly with a view to ascertaining the source of the Banff hot springs and their relation to the geological structure. The upper spring has of late years become irregular and intermittent in flow. As these springs are an important attraction, consideration is being given to the possibility of restoring and maintaining their flow, and Mr. Warren will endeavor to ascertain what remedial action should be taken. The strata near Banff also include a phosphatic bed which may in places be rich enough to be used for making land fertilizer.

E. M. Kindle will assist P. S. Warren at Banff, J. R. Marshall in Kananaskis area, and M. F. Bancroft in Windermere area in determining the succession and age relationships of the rock formations in these areas.

D. B. Dowling will make a detailed study of the coal seams and coal measures in Wind Mountain, a few miles south of "The Gap," near Canmore, on the Canadian Pacific railway. These measures contain bituminous coal of unusually good quality for domestic use and would be particularly suitable for consumption in Ontario if transportation ever becomes practicable. Dr. Dowling will also investigate various occurrences of lignite in southern Saskatchewan and near Souris, Manitoba.

E. J. Whittaker and *M. Y. Williams* will commence a careful revision of the geology of southern Alberta with the object of preparing a map and sections which will show the thicknesses, structure and distribution of the various formations as accurately as available data permit, The strata contain coal seams and supplies of natural gas, petroleum and water and an accurate knowledge of the geological structure is required for guidance of exploratory boring operations.

F. H. McLearn will study in detail the geological succession of the Blairmore coal-producing area, which affords a key for the interpretation of the geology of the coal measures of Alberta, and their associated rock formations. He will also collaborate with Mr. Whittaker and Dr. Williams.

C. M. Sternberg will collect fossil remains of dinosaurs and other vertebrate animals near Red Deer for the Victoria Memorial Museum at Ottawa.

Saskatchewan

J. S. DeLury will commence mapping an area of about 500 square miles southeast of Lac La Ronge. The area includes one of the belts of schists which in northern Saskatchewan and Manitoba constitute the most favourable ground for prospecting.

Manitoba

R. C. McDonald will continue the work begun last year of making accurate control surveys for a general geographical and geological map of northern Manitoba. A good geological map is needed by prospectors and explorers in the region in addition to the various detail maps of mineralized areas which have been prepared by F. J. Alcock and E. L. Bruce. The Air Board of Canada is expected to assist in this work by carrying supplies during the summer, making observation flights and taking photographs from the air.

F. J. Wright will continue the systematic geological mapping on a scale of one inch to the mile of the Rice Lake mineral area east of Lake Winnipeg, which he commenced last year. The area contains deposits of gold and copper-nickel ores whose relations to certain granite and gabbro intrusive rocks have already been fairly well established. Dr. Wright is now preparing maps of the district that will show the distribution of these formations which are of such significance to prospectors.

Ontario

E. E. Freeland will complete the topographic mapping on one inch to the mile of an area of over 200 square miles around Port Arthur and Fort William. A topographic map should fill many engineering and other requirements in this important and rapidly developing industrial centre. Mr. Freeland will also make accurate control sur-

veys for a series of standard one mile maps between Port Arthur and Nipigon.

T. L. Tanton will make a detailed geological survey and investigation of the mineral resources in the area around Port Arthur and Fort William that is being topographically mapped by Mr. Freeland. Particular attention will be given to the clays, shales and other structural materials which are becoming of increasing importance to the two cities.

E. Thomson will commence the systematic geological and geographical mapping and investigation of the mineral bearing possibilities of an area just north of Woman River, on the main line of the Canadian Pacific railway. The area comprises part of a large "Keewatin" area in which iron formations and gold-bearing veins have been found and which appears to deserve the attention of prospectors.

The Huronian formations that extend along the north shore of Lake Huron from Sault Ste. Marie to Sudbury are of considerable economic interest since they contain occurrences of copper, gold and iron ores and inexhaustible supplies of high-silica quartzite. A thorough knowledge of the stratigraphy of these formations is also of fundamental importance to geological investigation in northern Ontario. Attention has been given to the investigation and mapping of this Huronian region by the Geological Survey since 1914, and will be continued this year.

R. C. Emmons will investigate and map in detail an area lying east of Echo lake and north of Bruce Mines and Thessalon.

G. W. Bain will do similar work in another area just north of Webbwood. This area includes a body of considerable size of basic igneous rock similar to the nickel-bearing intrusive of Sudbury district.

T. T. Quirke will commence the detailed geological mapping on one inch to the mile of an area of over 400 square miles north and east of Killarney. The area is of importance in the study of Precambrian geology because it occupies part of a little known gap between the Huronian region of lake Huron and the Grenville region of eastern Ontario. Owing to its location on Georgian bay and the cheap transportation facilities to Canadian and United States ports afforded by the Great Lakes, low-priced mineral materials, such as feldspar, high-silica quartzite, granite and other building materials, which occur or may occur in the map-area, have greater possibilities of development than deposits situated less favorably. Special attention is therefore being given by Dr. Quirke to occurrences of this character.

S. C. McLearn will make a triangulation survey of the area which is being mapped by Dr. Quirke for the purpose of establishing accurately located points throughout the area to which the less precise surveys of the lakes, streams and other features will be tied and controlled. This will increase the accuracy of the map and give it permanent value as a contribution to the primary mapping of Canada. The triangulation survey will be connected with stations in Sudbury area and with a detailed resurvey of the coast and islands of Georgian bay made in 1915-1918 by the Ontario Government.

E. M. Kindle will study the succession and age relationships of the Palaeozoic formations of northern Ontario on the Kabinakagami, Albany and lower Abitibi rivers.

M. E. Wilson will continue the systematic geological mapping of the Precambrian formations in the vicinity of Madoc. Examination will be made of the gold-arsenic deposits at Deloro, the pyrite deposit at Sulphide and other mineral occurrences.

E. V. Ellsworth will continue the study of the radioactive minerals of Ontario and Quebec. He will also continue a systematic investigation of Canadian occurrences of the minerals of the rare elements, cerium, beryllium, zirconium, etc. New uses for these elements and their compounds are being found and there is an increasing demand for information regarding the sources of supply.

Quebec

During the development of the Porcupine, Kirkland Lake, Matachewan and other gold-bearing areas in northeastern Ontario, since 1910, it has become fairly well established that the gold deposits are related to small bodies of granitic rocks intrusive in the "Keewatin" schists. These schists extend eastward into Quebec and appear to be invaded by granitic rocks as in Ontario. Last year the Geological Survey commenced detailed mapping of part of the Keewatin area in Quebec immediately adjacent to the Ontario boundary with a view to mapping as many as possible of the granitic intrusives, and distinguishing drift-covered parts from parts where bedrock is exposed, and thus facilitating prospecting operations. Either by coincidence or in consequence of this action vigorous prospecting commenced in the area selected for mapping and before winter several discoveries were reported.

The commercial value of these discoveries has not yet been ascertained but this year there are indications of still greater prospecting activity. To satisfy the requirement for geological maps and information four Geological Survey parties will be placed in the district.

H. C. Cooke will make a detailed examination of all known occurrences of gold in the new district with a view to determining their extent and character, their geological relationships and the factors governing their origin and distribution. If time permits a comparison will be made with some of the Ontario deposits.

W. F. James and *R. Harvie* will each continue systemmatic geologial mapping of the country eastward from that which was surveyed last year, maps of which are now available.

R. Bartlett will make accurate instrumental surveys of the principal lakes and streams in the area to be examined by Drs. Cooke, Harvie and James. An insufficient amount of exact control surveys existed last year to enable satisfactory geological maps to be compiled, but this lack is rapidly being satisfied by the Department of Lands of Quebec, which is having surveys made of the townships boundaries and waterways. This survey work is being supplemented by Mr. Bartlett.

E. Antevs will study the stratified clay deposits of Quebec and Ontario which were formed during the northward retreat of the great ice sheets that covered Canada during the Ice Age, for the purpose of measuring in years the time which has elapsed since the ice sheets commenced their retreat. An ingenious method of age determination was developed in Sweden by Baron Gerard de Geer whereby the period of ice retreat in Europe has already been computed. An effort is now being made to make a similar determination for North America so as to add to our knowledge of the Ice Age in the northern hemisphere. Dr. Antevs, a pupil of Baron de Geer has spent the past two years studying the problem in United States and has carried his investigation northward to the Canadian boundary. This year, with some assistance from the Geological Survey the work is being continued in Canada and an opportunity afforded to learn the special methods employed.

F. A. Kerr will commence the detailed geological mapping of an area east of Lake Memphramagog and will investigate the mineral bearing possibilities of the area.

K. G. Chipman will complete the topographical mapping on a scale of one mile to the inch of an area of about 200 square miles around the Federal Zinc and Lead Mine, in

Gaspé. Mr. Chipman will also continue standard topographical mapping in the asbestos bearing region of southern Quebec.

F. J. Alcock will map the geological formations and investigate the mineral possibilities of the area in Gaspé which is being topographically mapped by Mr. Chipman. He will also examine various reported occurrences of copper and other minerals in Gaspé adjacent to the map-area.

J. D. Dart with the assistance of Professor Charles Schuchert, of Yale University, will study the succession of stratified formations on the south coast of Gaspé between Port Daniel and Newport. This work is contributory to the general understanding and correlation of geological knowledge of the Palaeozoic formations of eastern Canada.

J. B. Mawsley will map an area of anorthosite (a variety of intrusive igneous rock) north of Baie St. Paul and examine in detail the deposits of titanium ores which are associated with this intrusive mass.

A. T. McKinnon will collect in various parts of Quebec and Ontario specimens of ores, minerals and rocks for exhibit in the Victoria Memorial Museum at Ottawa and for preparation of educational collections which are distributed to schools, local museums, prospectors' associations and other institutions in Canada.

New Brunswick

W. S. Dyer will map on one mile to the inch the Minto coal basin, and will investigate in detail the structure and succession of the Coal measures, the coal seams, and coal reserves. This is contributory to a systematic investigation of the coal resources of Canada.

A. Anrep will survey and estimate the contents and commercial value of 4 peat bogs near Fredericton, Chatham, Shippigan and McAdam Junction. This is in continuation of a systematic survey of the peat resources of Canada.

Nova Scotia

E. R. Faribault will continue the systematic geological and geographical mapping of Nova Scotia on the scale of one mile to the inch. This work has now been carried westward as far as Middleton. During the present year Dr. Faribault will complete the Middleton and Paradise sheets and commence the Annapolis Royal sheet. He will also complete a detailed examination of the Nictaux-Torbrook iron range.

S. C. McLean will establish a series of precise triangulation points in the three areas which are being mapped by Dr. Faribault. This system of fixed points will be connected with the primary triangulation stations of the Geodetic Survey of Canada and will furnish an accurate control and give permanent value to the surveys of roads, lakes, streams and other features that are being made by Dr. Faribault.

W. A. Bell will complete the detailed geological investigation, begun last year, of the structure and stratigraphic succession in the Pictou coal area, near New Glasgow. He will also continue his work of correlating the coal seams of the Sydney coal area.

A. G. Haultain will commence the survey of a topographic map of the Springhill coal area on a scale of one mile to an inch. He will also make surveys for a detailed map on an engineering scale of the area in which mining operations are being carried on. These maps are required as base-maps for geological work which will follow, and the detailed map should also be of service in the conduct of mining operations.

M. E. Hurst will make a systematic study of the arsenic deposits in Nova Scotia, Ontario and other parts of eastern Canada. There is an increasing consumption of arsenic and a corresponding demand for an inventory of the available supplies of arsenical ores in Canada.

POSITION OPEN IN DEPARTMENT OF MINES

The following position is open in the office of the Deputy Minister of Mines, Ottawa. It is a desirable position for a man with a scientific bent and training as the appointee, if the right man, is in line for promotion to Head Clerk at a stated salary of $2,400-$2,880.

5641. — Principal Clerk (Male) for the Administrative Branch of the Department of Mines, at an initial salary of $1,800 per annum, to be increased at the rate of $120 annually to maximum of $2,280, this salary to be supplemented by whatever bonus may be provided by law. The qualifications required include education at least equivalent to high school graduation, and preferably university training in scientific subjects, with one year of experience in connection with the mining, metallurgical or chemical industries or related governmental work.

Applications must be in the hands of the Secretary of the Civil Service Commission, Ottawa, not later than July 26th. Forms may be had from the Secretary, or from the postmasters in the principal cities, or from offices of the Employment Service of Canada.

SASKATCHEWAN HAS RAW MATERIALS FOR MAKING FIRE-BRICK, TILE AND POTTERY*

The province of Saskatchewan is the fortunate possessor of extensive deposits of clays which may be looked upon as important raw materials. These will aid in the industrial development of the Prairie Provinces and should prove to be of great value. There are clays suitable for the manufacture of good building brick, structural and agricultural tile and sewer pipe; ball clays and stoneware clays for the manufacture of pottery, and also refractory clays for fire-brick.

During the past twelve years, the clays of Saskatchewan have been under investigation by the Dominion Department of Mines. Attention was first directed to the high-grade clays of the province by Mr. Joseph Keele in the report on his investigation of the clays and shales of the western provinces. A more detailed study of the clays of southern Saskatchewan was made later by Mr. N. B. Davis.

Under the auspices of the Provincial Government, the University of Saskatchewan has recently established a ceramic department, with Professor W. G. Worcester in charge, for the purpose of carrying on extensive tests on the clays of the province and to provide a course in ceramic engineering which is designed to fit men to supervise modern clay industries.

Interest has lately been aroused in regard to fire-bricks. Prof. Worchester has supplied bricks for tests in a locomotive of the Canadian Pacific railway. These will be submitted to a rigid endurance test, and examined at the end of each run. He states that, if they stand the test, they may displace millions of dollars' worth of imported bricks, but he reserves definite prophecies until the final results are known.

* Prepared under the Direction of Dr. Charles Camsell, Deputy Minister of Mines, by Dr. A. W. G. Wilson, Chief Engineer, Mineral Resources Division, for "Natural Resources."

A copper smelter to treat 6,000 tons of ore a month is in course of erection in Papua at Bootless Inlet by the New Guinea Copper Mines, Ltd. The ore contains 4.6% copper and $2.50 per ton in gold.

BOOK REVIEW

THE ORE MAGMAS, A Series of Essays on Ore Deposition, by Josiah Edward Spurr — McGraw-Hill Book Company, 370 Seventh Ave., New York—two volumes, 915 pages.

In the discussion and explanation of ore deposits the theory of magmatic segregation has of late years been used less and less, its place having been taken by the idea of concentration from surrounding rocks or from deeper-seated parts of the magma, the concentrating agent being water. A classical example of the change in the trend of opinion is the copper-nickel ores of the Sudbury region. The earlier reports on these well-known ore-deposits seemed to leave no doubt as to their origin. They were described as segregations from the great norite laccolith. But, as time went on, evidence accumulated that the process had not been quite so simple, and the tendency of late has been to attach more importance to concentration by circulating waters and less to magmatic segregation.

In a two-volume book that gives the conclusions reached after a life-time of field experience, Mr. J. E. Spurr now brings us back to magmatic segregation as the principal method of ore-deposition. The title of the book, *The Ore Magmas,* leaves no doubt. The author finds little if any evidence of the concentrating action of circulating waters. The conclusions he reaches, based as they are upon his own unusually extensive observation, will be received with respect. The argument will impress, if it does not always convince. "So far as I have seen," a phrase frequently used in this book, is an expression of the caution and the modesty of the author. "These observations and conclusions, then, represent the gist of thirty years' study of ore deposits, mainly in the field" (Foreword, p. v.).

The author begins by pointing out that a series of dikes in Forty Mile Canyon, Alaska, of the same age, show a gradation from dark rocks composed mostly of hornblende, through hornblende granite, to quartz-feldspar dikes, and finally quartz dikes, in some of which he found gold. This is a case of *magmatic differentiation.* "The seasoned field geologist knows it to be a fact that igneous magmas segregate into unlike portions, which crystallize into rocks differing considerably in mineralogical and chemical composition." (p. 63). So far the author has plenty of company, but he applies this idea of magmatic differentiation to explain quartz veins, considering them as having been filled in at a later stage than the dikes but by the same process, not by circulating magmatic waters, but as it were at one blow by the solidification of a magma kept in the liquid condition to this late stage by the considerable proportion of water present. "The discovery of free gold in certain quartz veins of this type showed to me that not only the quartz veins but the gold-bearing quartz veins were the result of magmatic differentiation; and, finally, the association of gold and quartz in quartz veins became clear to me for the first time," (p .64)—a happy conclusion, for in an earlier paragraph the author states, "any explanation of ore deposition must explain the close association, in veins, of quartz and gold (and other metals) to be even an acceptable working hypothesis" (p. 61). The gold was present in the original magma, accompanied the quartz in the process of differentiation, and was deposited along with it when the whole mass became solid. One striking argument for this theory of vein formation is the presence in veins of angular fragments of the wall rock totally unsupported by the walls, indicating a viscous condition of the vein matter at the time the fragments broke off or a solution heavy enough to support them. It is hard to account for the position of these fragments, if the veins were filled by the deposition of quartz from circulating solutions.

In brief, the author's theory is that veins are filled directly with differentiated magma, and that exceptionally the magma contains enough gold to make the vein auriferous. The same origin with differences in details is put forward for other ore deposits.

Igneous intrusions are due to the pressure exerted by the magma, telluric pressure, associated by the author with gas pressure due to the presence of water and other gases. The magma thrusts itself powerfully into the rocks, causing folding and other disturbances. Fracture and faulting are to be explained by this same force. The flow of rock under the uplifting pressure of the intruding magma can be seen in some cases to have been vertically upward as well as horizontal. There is no evidence that open cracks have been filled with vein matter, but ample proof that the magma forced its way into the rock, cracking it and pressing it apart. This idea had already been used in explaining dikes, laccoliths, etc. The author now applies it to vein formation.

Ore magmas are special cases of magma in general There are subcrustal tracts rich in the various metals. A mass of magma moving over one of these picks up more or less of it. It intruded itself into the overlying rocks, and a differentiated part into which the valuable material has been concentrated forms the veins. Ore bodies having no obvious connection with intrusive rocks may still come under this theory. "The usual lack of igneous rocks in connection with the lead-zinc deposits of the Mississippi Valley and elsewhere in the world is not a proof that they are of non-magmatic origin." The punching up of the limestone into domes may be taken as evidence of the action of a hidden intrusive mass.

In discussing metallogenetic epochs the author points out that they were brief periods of ore deposition separated by great stretches of geologic time, during which erosion and sedimentation went on, but no ore deposition. This disposes of the theory of general ore depositions by circulating waters of surface origin, and also of the theory that minerals are collected by such waters from rocks through which they are disseminated. (p. 386). Ore deposition periods are coincident with times of widespread igneous intrusion, and therefore are also separated by great periods of geologic time, and similarly rock deformation (p. 387).

The fascinating story of North America as read from the rocks is told on page 392 and the following pages. In the Colorado region, for example, there was a succession of quiet sinkings and risings with erosion and sedimentation, till late Cretaceous times, when a final rise was the prelude to geological revolution and a period of ore deposition. Such catastrophes were due, according to the author, to migration on a vast scale of the sub-oceanic magma (pressed out by the accumulating weight of sediments?) to the continent, there to be thrust upward by the impelling force behind.

These two volumes, written in a simple, familiar style, without undue indulgence in technical terms, are the interesting record of a long life of close and intelligent observation in the field. They are not so much the elaboration of a theory as the description and correlation of facts, for the observation of which the author had unique opportunities. He brings forward the theory of magmatic segregation or differentation in a new way, and in his own words, (p. 507) "*Exit,* then, and *vale,* so far as I am concerned, the underground, surface-derived water below the superficial rock zone as a cause of the primary concentration of ore deposits."

SELF-DEPENDENCE IN FUEL NEEDS

"Natural Ressources," an official publication of the Department of the Interior, Ottawa, publishes in its July issue the following summary of the recent interim report of the Dominion Fuel Board. This official resumé follows:

The Dominion Fuel Board, which was organized last winter under the chairmanship of Dr. Charles Camsell, Deputy Minister of Mines, has issued a report which is of great importance in emphasizing as it does the rapidly approaching necessity of self-dependence in the matter of fuel resource. Canada has computed coal reserves of 1,234,269 million metric tons against a present consumption of about 32 million tons annually, but this is unfortunately concentrated in the western and eastern extremities, leaving the populous industrial sections of Ontario and Quebec dependent so far on other sources of supply.

To remedy this state of affairs, the Board stresses th greater use of Maritime and Western coals, the importation of Welsh anthracite, the coking of bituminous coal for domestic purposes, the establishment of central heating plants, and the more extended use of peat and wood as auxiliary fuels.

Maritime and Western Coals. — While the coal of the Maritime Provinces is bituminous and therefore as a domestic fuel is subject to the same prejudice as United States bituminous, the Board believes that this coal should be used in the making of a domestic coke and would thus materially assist in the solution of the domestic fuel problem. Alberta coal ranges from lignite to semi-anthracite, and has during the last few years successfully competed with American anthracite in Manitoba. Trial shipments have also been made to Ontario. The crucial problem here is that of transportation costs.

Coking Bituminous Coal for Domestic Heating. — The Board is making a thorough investigation as to the feasibility of establishing by-product recovery coking plants at such points as Montreal and Toronto for local consumption and for shipment to tributary territory. The abundant bituminous resources of Nova Scotia, New Brunswick, and the United States would be used for this purpose. Recent improvements make domestic coke much superior to ordinary gas-house coke and of approximately the same heating value as anthracite. This coke has practically displaced anthracite at a number of points in the United States, including St. Paul and Minneapolis from which points shipments are being made to Winnipeg.

Central Heating Plants. — These, it is calculated by the Board, would reduced the cost of heating by allowing the use of low-grade fuel; the delivery at one central point; by the disposal of ashes and the use of trained engineers. Such plants are in use in the United States, in Europe and in various parts of Canada, the best known here being the plant in Ottawa which heats the Parliamentary and other Government buildings.

Welsh Anthracite. — This is of higher grade than Pennsylvania anthracite, but breaks up more in transit. The best varieties contain about 90 per cent. carbon and 3 per cent. ash. Welsh firms are now canvassing the situation.

Peat. — The Board is of the opinion that peat could be used to advantage in the fall and spring months and, if the results already accomplished experimentally are not sufficient to induce private capital to engage in the industry, further encouragement should be given by the governments concerned.

Wood. — It is stated that the wood resources of Canada could be utilized to a greater degree in supplying a portion of our fuel needs.

The report concludes by warning the public of the false sense of security engendered by an easing in the anthracite market and urges the need of educating our people away from dependence on a single source of supply.

LONG LIFE PREDICTED FOR GOLD MINES

Preparatory to issuing the new securities of Northern Canada Power recently, the Dominion Securities Corporation, which bought the issue, made inquiry of Mr. J. B. Tyrrell as to the status of the northern gold-field. Following is his letter, which is a striking profession of faith in the gold mines of Northern Ontario:

"Northern Ontario has now attained a permanent position as one of the great gold mining countries of the world. Large areas of it are known to be underlain by gold-bearing pre-Cambrian rocks in which a few rich producing mines, namely, the Hollinger, McIntyre, Dome, Wright-Hargreaves and Lake Shore, etc., have been opened up, while others now in process of development will soon be added to the list of producers. The ore in these mines will doubtless be found to extend downwards as far as favourable country rock continues, with no certain prohibitive mining limit but that made by the heat of the interior of the earth.

"As examples of deep gold mines in pre-Cambrian rocks in other parts of the world, may be cited: The Morro-Velho Mine in Brazil, owned by the St. John del Rey Mining Company, which has been working for more than one hundred years, is now 6,726 feet deep and is still in very rich ore; the group of mines on the Kolar Gold Field in Mysore, India, which have been working for forty years, have produced gold to the value of nearly $300,000,000 and are now working at a depth of 6,000 feet; the group of mines at Kalgourlie, West Australia, which have been operating for thirty years, have produced gold to the value of about $350,000,000, and are working at a depth of about 4,000 feet; the Homestake Mine in South Dakota which has been operating for forty-five years, has produced gold to the value of about $170,000,000, and is working at a depth of 2,000 feet without any diminution in the quantity or grade of the ore. Therefore, considering that these great gold mines or groups of mines have been operating for many years in pre-Cambrian rocks very similar to those of Northern Ontario, that they have all reached great depths, and that their ore is continuing downwards, we may confidently rely on the permanence of our Ontario gold mines which are also in Pre-Cambrian rocks, and which, down to the depths to which they have yet been worked, are following closely the laws applicable to the other mines mentioned above.

"The Ontario gold mines which are producing, were all discovered by natural outcrops of ore-bearing veins. Vast areas where such outcrops may also occur have not yet been examined by prospectors and their possibilities are still unknown, and besides such "rocky" areas, all travellers in Northern Ontario will agree with me that 90% or more of the pre-Cambrian rocks are covered with a thick overburden of soil or detritus which completely hides them and renders casual discoveries of ore quite impossible; nevertheless these rocks so covered and hidden from view may contain just as many mineral deposits per square mile as those which are exposed on the bare rocky hills and ridges.

"The mines which have already been discovered will doubtless be working for generations. In addition to these, considering the great extent of the covered and unpros

pected areas of pre-Cambrian rocks relative to the prospected areas, and the possibilities of these covered and unprospected areas for containing ore, I am quite confident that many more rich mines will yet be discovered and that Northern Ontario may be depended upon as a great mining country for centuries to come."

SOUTH AFRICAN CAPITAL IN KATANGA MINES

Mr. Robert Williams, who has been intimately associated with the development of the Rand goldfields under the leadership of Cecil Rhode, is now one of the principals in the development of the Katanga mineral deposits, in association with M. Jean Jadot, President of the Union Minière Company. He and his associates have put millions of pounds into the Katanga enterprises, having built railroads and towns as well as constructing smelters and developing mines. An account of his recent visit to Elisabethville in the mining region of the Congo is given in the *South African Engineering and Mining Journal*. In addressing the guests at a banquet held in his honour, Mr. Williams said, in part:

"When I last visited Elisabethville, it was to inaugurate the smelting operations. When the molten stream began to flow I turned to a companion and remarked, 'This is the beginning of the stream that is to completely revolutionize Central Africa.' To grasp the meaning of this industry and its future the factors which have been the cause of success so far and which will make for greater success in the future, one must look back as well as forward. One must bring one's experience gained in the other industries further south. This is the fourth mining industry in Africa I have grown up with, and I venture to say that this one will be the greatest of them all; but only if the experience gained at the other three is profited by. What was that experience?

"First, that a great industry can only be made a success by encouraging every adjoining country as well as your own country, to develop everything your industry may require, whether it is a railway, a coal mine, a sulphur mine, beef or food of any sort. You will require them all as your own country, with its rapidly developing industries, will never be able to supply the needs of this great industry as I picture it in the future. Indeed, this industry would not be so far advanced as it is to-day had not Rhodes pushed on his Cape to Cairo railway, and Wankie Mines, from which your coke comes, would not be in existence to-day for the same reason.

"Secondly, you will require to encourage from now onwards all natives from your own country and from surrounding countries and to gradually acclimatize them to this country as the industry grows in order to have the 60,000 or 100,000 natives this industry will ultimately require. You will never be able to depend on any one source of native labour. Most of your sources of native labour will be required for the rapid development of railways and other industries in your own country. It is also quite certain this industry cannot depend on one railway as it does at present.

"Thirdly, the knowledge gained in the goldfields of their geological occurrence was necessary in order to guide my staff and myself to this country and its great copper belt. In fact, when Cecil Rhodes asked me to find mineral wealth to assist his Cape to Cairo railway north, I looked at the map of Africa and saw a great divide forming the headwaters of the Congo and Zambesi Rivers and realized that divide was really a du plication of the divide which forms the head-waters o the Limpopo and Orange Rivers further south an which constitutes today the Rand Goldfields.

"If it was a great effort to expose the mineral weal of these mines, situated as they are over 1,000 m. fr from any seaport or railway terminus, it was a st greater effort to develop work and finance th Railways had to be built, large installations had to b erected, villages created with water supplies over 25 miles of a continuous reef. Native labour had to b organized and hospitals for white and black staffs ha to be erected. Water power had to be investigate and great epidemics had to be fought. Millions had t be found for this purpose, and these millions wer found chiefly as the result of the efforts of my re pected colleague, Monsieur Jean Jadot, President o the Union Minière Company, and myself."

The copper ore was first discovered as isolated ou crops, which were afterwards found to be parts of continuous "reef", extending for a distance of 2 miles. "About ten miles out of 250 miles of this coppe belt has given a development of 50,000,000 tons of or containing about 4,000,000 tons of metallic copper. Many other deposits have been located, but awa development. Only high-grade ore is being used a present at the smelters, whose capacity is 50,000 ton of copper per annum. Mr. Williams predics that thi will be vastly increased as railway communication i improved.

RETURN FROM RAND INVESTMENTS

In a paper presented to the Chemical, Metallurgica and Mining Society of South Africa, R. A. Lehfeld gives further data explaining his calculations of th return to capital from the Rand gold mines. The aver age is, he estimates, 6.20 per cent. Twelve mines hav yielded more than double the investment; 30 have re turned more than the investment; 16 have yielded ov half the investment; 25 have yield under half th investment; and 12 mines have made no return at al The figures used for this calculation are official return from 1907 to 1921.

WATER POWER IN THE ACUTE FUEL AREA

The "Acute Fuel Area" has now narrowed itself dow to the provinces of Ontario and Quebec and it is of in terest to observe the effect of water power development relieving the situation in those provinces.

In Ontario the developed water power has increase from 430,000 h. p. in 1910 to 1,220,000 h. p. in 1922 184 per cent. and in Quebec from 315,000 to 970,000 215 per cent.

These coal-less provinces import from abroad over 9 per cent of their coal requirements, but in Ontario th coal equivalent of developed water power substantially ex ceeds the total coal consumption and in Quebec it is mor than twice the coal consumed. The total saving in coal a an average cost of $10 per ton is over $192,000,000 pe annum in these two provinces alone.—"Natural Resources

Oxygen gas produced by the method of liquefactio from the air costs from 75 cents to $1.00 per thousan cubic feet. When a method is devised of making it a a cost of 25 cents per thousand feet, it will be availab for many new and important industrial uses.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHWESTERN ONTARIO

The Schreiber gold area is attracting increasing attention as development work proceeds on the various properties now being opened up. Mining men from Porcupine and Kirkland Lake are not infrequent visitors, while mining engineers and investors from various parts of the United States are taking a keen interest in this field.

The Schreiber Gold Mines, Ltd., have taken up their option on the McKellar-Longworth property, and have made the first payment. They have been carrying on an active development campaign since March 1922. The work to date consists of extensive stripping and trenching, sinking, tunneling and cross-cutting, together with general surface improvements. The work so far done shows that the vein system consists of a series of parallel veins in a zone 400 feet wide, crossing the property from east to west. The underground work consists of No. 1 tunnel, which is now in 135 feet, cross-cutting the vein system, the objective being the north boundary of the mineralized zone. No. 2 tunnel is being driven 500 feet west of No. 1 on the same zone, and is now in 50 feet, exposing the same formation and veins as found in No. 1. An open cut has been made on the hillside above No. 2 tunnel, from which 15 tons of high-grade ore was taken, together with 5 tons fom No. 2 tunnel, and sent to the Timiskaming Testing Laboratories at Cobalt, the whole 20 tons giving an average value of $12.40 per ton. No. 3 shaft is 6′ x 8′ between timbers, and is now down 20 feet, midway between the two tunnels, on a vein paralleling No. 1. The latter is from 3 to 5 feet in width. The westerly extension of this vein, described as No. 2 is from 8 inches to 18 inches in width, carrying a higher grade of ore than No. 1. No. 4 shaft is 250 feet south, and midway between the tunnels, 6′ x 8′ between timbers, and is down 50 feet. Visible gold shows all the way down. 225 feet south of No. 4 shaft there occurs a vein of schist and quartz 16 feet wide, with well defined walls. This vein has been opened by trenches at various points and shows free gold wherever exposed. This latter is the largest and richest vein on the property.

A good road system has been provided, together with a complete set of camps to accommodate 30 miners, an office building, assay office, cottages for employees and stables.

A Diesel engine, with capacity for running 4 drills, pumps, and all power requirements has been installed.

The campaign of development as outlined and now under way will consist in pushing both tunnels until they cut all veins in the ore zone, and sinking to the 200-foot level, where lateral work will be commenced. The drift will give a back of 300 feet.

The work is being carried out under the direction of Charles Randall, recently of the Dome Mines, Porcupine.

The Tonapah Mining Company, who are also operating properties at Kirkland Lake, have secured mining claims A. L. 54, and R681, and are negotiating for a group of surrounding claims in the Schreiber field. These properties are about one mile north of the Schreiber Gold Mines' lands, and abut on the Canadian Pacific Railway, about one mile east of Schreiber. This company have a crew of men at work stripping and trenching preparatory to commencing underground development.

Louis Fenning, representing New York interests, controls 16 claims immediately east of the Tonapah group. He has put down a 7′ x 11′ shaft 110 feet, the objective being the 300-foot level. The shaft is being put down on a strongly defined, well mineralized veins carrying good gold values. Lateral work will not begin until the objective is reached. The property is equipped with a 4-drill compressor, steam hoist, and most complete camp equipment.

Rayton E. Horton, of Patterson, N. J., is carrying on surface work by way of stripping and trenching and general surface improvements preparatory to beginning underground development, on R608, R609 and R610, situated about one mile east of the Schreiber Gold Mines properties.

The Tonapah and Horton developments are under the direction of William Longworth, formerly of the McKellar-Longworth property.

BRITISH COLUMBIA

Electrical Power for Stewart — Water-power is being developed near the town of Stewart, gateway to the Portland Canal mining district, in order that a lighting and a telephone system may be provided for residents of the community. The project is being put through by the International Electric Co. Ltd. and it is understood that the funds needed are being found chiefly in England.

Trail Ore Receipts — Ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co. of Canada, from the 15th to the 21st June totalled 6,129 tons, made up as follows:

Alamo, Alamo	45 tons
Company Mines	5592
Knob Hill, Republic Wn.	51
Lone Pine, Republic Wn.	171
Quilp, Republic Wn.	100
Ruth, Sandon	48
Silversmith, Sandon	79
Soho, Rambler	33
Silver Bear, Zwicky	10
	6,129

Whitewater Mine to be Worked by Owners — John R. Retallack, of the Whitewater Mines, near Kaslo, has announced that the mine is to be re-opened by the company and put on a producing basis. This is one of the Kootenay properties that has been worked recently by leasers. In regular operation it has a production record of 34,477 tons of lead ore shipped with a net value of $1,579,213, and 16,086 tons of zinc ore with a net value of $209,595. From this production a profit of $622,515 was derived. This record is a sample of the results obtained from the development of a Slocan ore-body. Thus far the ore has been taken from a small area of ground and it is anticipated that the mine has years of life ahead.

Shafts for Kootenay Property — The Rio Tinto mineral properties, situated in the Salmon River Valley, West Kootenay, are reported to have passed into the

hands of an American syndicate at a price of $60,000. The development done on two well defined veins has exposed them on seven claims. The values are chiefly in silver and lead with a small amount of gold. The new owners intend surveying the property and installing the machinery necessary to sink two shafts, which, it is calculated, will be put down 350 feet. This work done, the properly should be in shape for steady production.

Engineer Mine Action Dismissed — The latest action involving title to the Engineer Mine of Atlin has been dismissed with exceptional curtness. Robert E. Williams, of Milwaukee, and his brother Horace K. Williams, of Los Angeles, who sought a declaration that as relatives of the deceased they were entitled to one-third interest in the estate of the late James Alexander, have been informed that their action is "frivolous, vexatious and an abuse of the process of the court." The plaintiffs are brothers of Abie Alexander who was known as the wife of Capt. Alexander but proof of whose marriage has not yet been found notwithstanding diligent search throughout Canada and the United States. Thus, it would appear, another legal obstruction to the development of this British Columbia gold property is removed.

Babine Bonanza Tunnel — James Cronin, mine operator, has returned to superintend further development of the Babine Bonanza, a property near Telkwa said to have great promise. A long tunnel is being driven 1,000 feet and is being continued at a depth of 300-odd feet under the surface workings, to tap the ore-bodies.

Rambler-Cariboo Producing — The Rambler Cariboo Mine, Slocan district, again is being operated. Production on a small scale will be maintained while development will be energetically prosecuted.

Gypsum Quarry to Operate — The gypsum deposit of Salmon River, near Vernon, central British Columbia, is to be exploited, according to report, plans being well in hand to that end. A. W. Davis, resident mining engineer, in last year's report said that this would appear to be the premier gypsum deposit of the province's interior. There is a very large tonnage in sight. The Manitoba Gypsum Company are the owners and it has been their intention to furnish all the western demand for the material. Owing to delay in projected railway construction, the property has been standing idle, although developed and equipped and ready to ship on short notice. The material is a pure white gypsum (alabaster) in rock form. A typical analysis follows:

CaO	32.60 %
SO_3	46.87
H_2O	20.80
Insoluble	0.06
	100.33

Certificates for Coal Mine Officials — Examinations for the granting of First, Second and Third Class and Mine Surveyor's Certificates of Competency were held, under the provisions of the British Columbia Coal Mines Regulation Act, on the 29th 30th and 31st days of May, 1923 at Nanaimo, Fernie Merritt and Cumberland. The Board of Examiners has recommended that Certificates be granted to the following candidates who have obtained the necessary number of marks:

Second Class: Edward Morrison, Fernie; Daniel Morgan, Nanaimo; James Duncan, Fernie.

Third Class: Albert Bastian, Ladysmith; Henry C. Beard, Natal; William M. Frew, Nanaimo; John Chapman, Ladysmith; John B. MacLaren, Michel; Peter Hindmarch, Lantzville; William Gregory, Natal; J. J. Eccleston, Coal Creek; John Smellie, Michel; James Rallison, Nanaimo; John Pollock, Ladysmith.

Mine Surveyors: James S. Crosscombe, Coal Creek; Joseph Sandland, Nanaimo.

NOVA SCOTIA

The Steel Strike. — The labor situation in Cape Breton is now completely disarranged, and before matters settle down labor will find itself with a very humble and contrite heart. Already much of its vanity has evaporated and the swelled heads so noticeable during recent months have contracted at least to normal proportions. The last act of the drama is being staged with the British Empire Steel Corporation in a mood to cry, "Lay on, McDuff, and damned be he who first cries 'Hold.'" The curtain will fall, and when the confusion and the noise of oratory have cleared away there will be more wise men in Cape Breton than there have been for many a day. Already there are not a few disillusioned steel workers around Sydney, whose hopes are as water spilled on the ground. The one hundred per cent. strike so loudly proclaimed and long threatened has failed to materialize, and the joy of battle lasted only one short day. Eight hundred men refused the call to quit work at the steel plant, and when the strikers in their despair attempted to raid the plant and rush these men from their work, they were met with an opposition just as determined and more courageous than the mood any striker showed, for they themselves were driven by the remaining employees from the plant. The Sydney steel strike was broken the first day it began, and the desperation shown by the strikers proved that they fully realized their hopeless position. Mob violence played into the hands of the company, and lost the workmen the little sympathy that had been felt for their cause. Raids and rioting were answered by the bringing in of soldiers and provincial police. When these latter, after having been stoned and insulted, cleared the streets, the most horrible reports of brutality were put into circulation, and the collieries rang with stories of dead children and injured women. Strikers and civilians, it was stated, were all alike to the provincial police, and no one was safe on the streets of Sydney. The public circulation of these false reports has proved the undoing of the "red" leaders, Livingston and McLachlan, now in prison and awaiting trial in Halifax.

The Coal Strike. — The promise made by the miners' convention in New Glasgow a few weeks ago, to help the steel workers in case of a strike has been put promptly into effect. When the miners saw the Dominion Coal Co. taking the horses out of the mine they admitted they had made a mistake, but had not the courage to tell their leaders so. They may do this in another way. The men are not unanimous for a strike and have entered on the struggle with little heart and less hope of winning. The maintenance men, however, have in most case been withdrawn from the collieries. Many of these are filling up with water and gas. Secretary McLachlan is alleged to have stated to the Attorney-General of the province, when his attention was drawn to the damage that might occur through his action, that "the Company's property could go to hell". Although it is well known that the coal pile of 200,000 tons representing the work and wages of the

miners of the winter months is on fire, the district executive have likewise refused to give any aid in removing it. Indeed, it may be found that any attempt to ship this coal will meet with strong opposition from the pickets, and round this coal pile may rage a battle.

Small Poll in Wages Vote. — A vote in favour of the 1921 rates of wages taken by the miners on the second day of the strike showed less than half the vote of the membership polled. Some districts like Springhill, Pictou and New Waterford either did not vote at all or voted against the strike. The apathy of the general body of members showed that they are not in favour of violating the agreement, and had the voting taken place before the men came out on strike it would have showed a large majority against the strike. The rank and file today are asking one another why they are on strike and no one seems to be able to tell. District officers admit that their affairs are badly muddled and that they are unable to disentangle them and lead their followers onto firm ground. Each step only sinks them deeper and they seem to be awaiting someone to come to their relief. It may be that the International President may relieve one or two of the officers of their duties and ask others to fill their places. This solution is one that has long been talked of and is expected by a number of the locals.

Coal Strike is Directed Against Provincial Government. — Whatever may be said for the steel strike, nothing favorable can be said of the coal strike. The cause admits of no compromise as the strike is not against the coal company but against the provincial police, and the Province controls this body. Either the Province or the United Mine Workers must back down. Other classes of labor have just as much cause to agitate against the provincial police as the miners. If the police act wrongly, they must be held responsible by the Province and judged by them, not by any labor organization.

TREADWELL YUKON

The annual report of the Treadwell Yukon Company, issued on May 15th last, gives particulars of the Company's holdings in the Yukon and British Columbia. No. 1 shaft has been sunk to a depth of 300 feet, where a flow of water was encountered with which it was found impossible to cope. A 2,500-foot drainage tunnel is now being driven to intersect the vein at 500 feet in depth. No. 2 shaft, 400 feet south of No. 1, has been sunk to 100 feet. Between the two shafts shoots containing 40,000 tons of ore have been blocked out, with an average content of 93.4 ounces silver, 10 per cent lead, 12 per cent. zinc and 25 cents gold per ton. From this, 4,000 tons of high-grade ore of an average value of 230 ounces silver, 36 per cent. lead, 12 per cent. zinc and 60 cents gold per ton, has been bagged and shipped. The gross value of this ore is $175. a ton, and it is expected that the profit, after deducting freight, smelter and tariff charges, will be $100 per ton. It has been sent to the smelter at Bunker Hill, Idaho. A third and fourth shaft have been commenced, and are working in ore of average grade.

ALASKA COAL DISPLACES B. C. COAL

Coal mined in Alaska has been placed on the market, according to reports received from the Alaska mining station of the United States Bureau of Mines. It is now being retailed at Juneau, capital of the Territory, at a lower price than is asked for British Columbia coal. The coal being sold comes from the Suntrana field of Alaska. Further information is to the effect that the Suntrana coal is proving very satisfactory for household use.

IMPROVING THE EFFICIENCY OF THE BLAST-FURNACE

Through its investigations into (1) the reactions taking place at certain zones in the blast-furnace, (2) the effect and elimination of sulphur in coke, and (3) the use of oxygenated or enriched blast, the United States Bureau of Mines hopes to reach definite conclusions which will be of considerable benefit to the iron and steel industry.

At its Minneapolis experiment station the Bureau of Mines has conducted several smelting campaigns, these including the regular sampling and determination of gases at fixed planes in the blast-furnace, from which certain deductions can be made. Another run is under way during the present month. Trials are also being made with oxygenated blast.

The behavior and elimination of sulphur in coke is being studied at the bureau's Pittsburgh experiment station, this revealing some interesting facts regarding the absorption of sulphur by the iron sponge inside the furnace.

The possibilities of using oxygenated blast are many, and include (1) the elimination of hot stoves; (2) the use of an excess of coke to prevent chilling and freezing; (3) the elimination of sulphur; (4) allowance of the utilization of high-phosphorus ores; (5) improvement in Bessemerizing; and (6) lower cost. A committee of ten metallurgists, chemists, and engineers, including five Bureau of Mines men, is studying this phase, and will shortly issue a preliminary statement thereon.

DAVY SAFETY LAMPS UNSAFE

The Davy safety lamp, whose introduction into collieries in England over a century ago effected almost a revolution in coal mining, is now considered unsafe. In England it has been completely displaced by newer and safer types of safety lamps. A report of the United States Bureau of Mines (serial No. 2484) states that many are still in use in the United States and recommends that their use be discontinued as dangerous.

Papua and New Guinea, now under British control, are reported as rich in minerals. Gold and copper have been mined extensively, and osmiridium is now being obtained from placers.

Advertisements other than "Employment Wanted" or "Employees Wanted" will be inserted in this department at the rate of 20 cents per agate line (14 agate lines make one inch). $2.80 per inch, each insertion, payable in advance. Space measured from rule to rule. When four or more consecutive insertions of the same advertisement are ordered a discount of 25 per cent. will be allowed.

Advertisements of "Wanted Employment" or "Wanted Employees" will be inserted at the rate of two cents a word, net. Cash must accompany order. If box number is used, enclose ten cents extra for postage in forwarding replies. Minimum charge 50 cents.

FOR SALE

Gold property in Nova Scotia. Wide mineralized belt, 6 dwt. Recent shipment to Nova Scotia Technical College from seven-foot vein ran $18.00 per ton. Will sell, or will give interest to party willing to develop property and erect mill. Inspection invited. Particulars on request.

— PERCY WHITE, Stellarton, Nova Scotia.

Ontario's Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

Hon. H. MILLS, Minister of Mines

Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth $48,128,387, of which the metallic production was $27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

Year.	Value.	Year.	Value.
1891	$4,705,672	1906	$22,388,383
1896	5,235,003	1911	41,976,797
1901	11,831,086	1916	65,303,822

Dividends.

Dividends and bonuses paid to the end of 1921 amounted to $23,140,734 for gold mining companies, and $84,388,185 for silver mining companies or a total of $107,528,919.

Mining Regulations.

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Publications.

For list of publications, illustrated reports, geological maps and mining laws, apply to

THOS. W. GIBSON,
Deputy Minister of Mines.
TORONTO, CANADA.

KENNEDY

Dependable Castings

A great feature of Kennedy Castings is that they are thoroughly dependable. The guarantee is incidental — you can **RELY** upon their being always sound, clean and true.

Kennedy Castings are made in malleable iron, grey iron, steel, aluminum, brass and bronze.

WELLAND ONTARIO

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows Placer Gold, $76,542,203; Lode Gold, $109,647,661; Silver, $59,814,266; Lead, $51,810,891; Copper, $170,723,242; Zinc, $24,625,839; Coal and Coke, $238,289,565; Building Stone, Brick Cement, etc., $36,605,942; Miscellaneous Minerals, $1,358,839; Making its mineral production to the end of 1922 show an

Aggregate Value of $734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive $94,547,241; for five years, 1896-1900, $57,605,967; for five years, 1901-1905, $96,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for 5 years 1915-1920, $189,922,725; 1921, $28,066,641; for the year 1922, $35,158,843.

Production During last ten years, $339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing

VICTORIA, British Columbia.
THE HON. THE MINISTER OF MINES.

GREENING WIRE ROPE

Strength

The finest materials and careful workmanship that go into Greening's Wire Rope are the source of its unusual strength. Quality has been Greening motto for sixty years.

Adaptability

The B. Greening Wire Company have kept accurate record of all conditions under which their rope has been used. This data is available to users of wire rope without obligation and frequently saves them time and money.

Efficient Power Transmission

at the Engels Copper Co., Engels, Calif.

Efficient, reliable transmission of power means more than elimination of trouble; it really means increased production. Uninterrupted operation of blowers, grinders and conveyors reflects itself in the output records of the mill.

That's why, after experience with many types of transmission, the Engels Copper Company determined upon using Link-Belt Silent Chain in their mill four years ago.

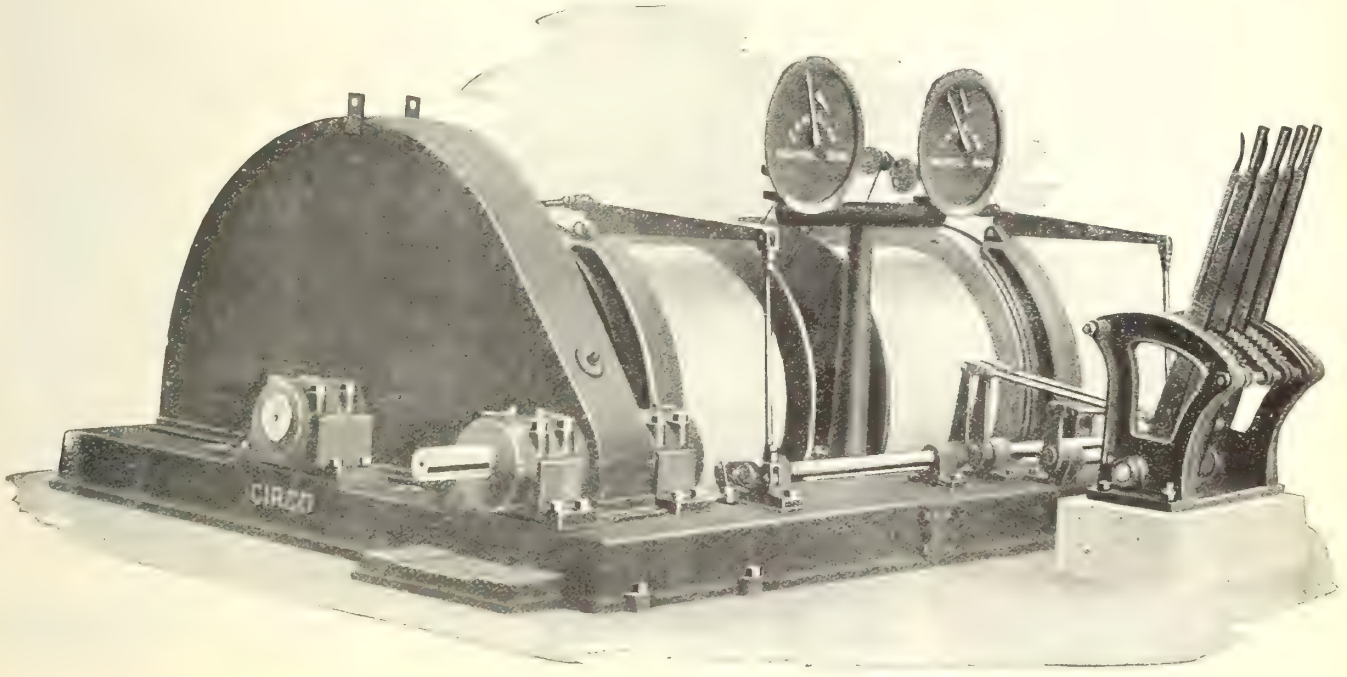
"CIRCO" HOISTS



Your hoist earns every dollar in your treasury

The earnings of your hoist depend on the tonnage it can handle and the tonnage it can handle depends on its power, reliability, and ease of control.

To design and build hoists capable of hoisting or hauling heavy loads continuously at high speeds to meet the requirements of modern mines and collieries calls for wide experience, engineering skill, and exceptional manufacturing facilities.

The size and type of hoist; how to equip it for best results and similar questions are most satisfactorily met by close co-operation on the part of the mine management and the hoist builder.

To the solution of such problems "Ingersoll-Rand" engineers bring the knowledge and experience acquired through more than half a century's association with the mining industry, plus the backing of an excellent manufacturing plant and a highly trained force of skilled mechanics, many of whom have been with the Company for twenty-five years or more.

No matter what the service, size, type of drive or equipment required, you can obtain a "CIRCO" Hoist to suit.

Consult our nearest branch.

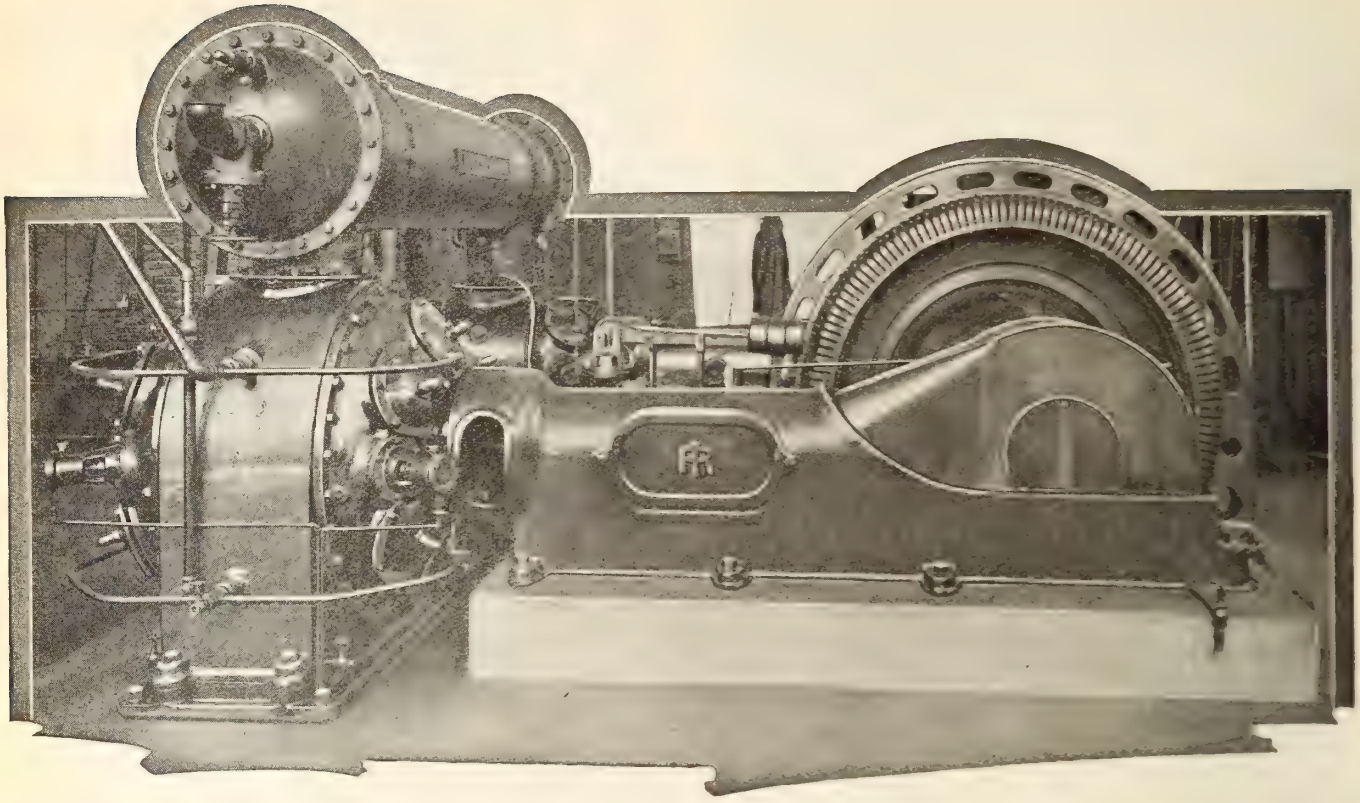
Ingersoll-Rand



Compressor Efficiency at All Loads

The demand for air is seldom steady even during any one day. During the year it is bound to vary in accordance with production.

Your compressor must be large enough to meet the present or the contemplated maximum demand. At the same time it should operate efficiently at partial loads so that the cost of air does not become excessive when the demand falls off.

Class "PRE" direct-connected, electric motor-driven compressors are extensively used where large volumes of air are desired. Regulation on the largest sizes is efficiently obtained in five steps, viz., full, ¾, ½, ¼ and no loads, by means of the patented Clearance Control. Smaller units are equipped with "Free Air Unloaders" which also permit efficient regulation at full, half and no load.

Similar units are also available for the compression of ammonia or other commercial gases.

Speaking of the compressor illustrated above, the Purchasing Agent of a large industrial plant says:—"We might also add that the machine has given us no trouble whatever since it was installed. It has given an excellent account of itself, although it has not been taxed to anywhere near its capacity. We believe we have a most excellent piece of equipment in this air compressor."

Serving Canada's Mining Industry

It is many years since The Imperial Bank of Canada, recognizing the importance of the Canadian Mining Industry and realizing the need of banking facilities for those engaged in its development, first opened a branch in Northern Ontario.

Since then the Imperial Bank's service has gradually extended until the mining interests in the rich area between North Bay and Hearst are now linked up by a complete chain of 12 branches.

This Bank's service to the mining industry is not confined to Northern Ontario alone. In all the mining areas throughout Canada the "Imperial" is rendering a valuable and complete financial service.

:-: EDITORIAL :-:

REPORTS FROM THE ROUYN GOLD FIELD

Development of the Rouyn gold district of Northwestern Quebec has been slower than was anticipated before the prospecting season opened. First of all, the season was two weeks late. Then the fires began to run, and many prospectors remained on the navigable waterways or stayed out of the district altogether until the worst threat was past. A number of parties lost their outfits in the fires and others saved them only by dint of moving to the protection of water.

An annoying impediment to progress in the western part of the gold belt is the continued inadequacy and disarrangement of the transportation service northward from Ville Marie on the Quinze and Kinojevis rivers, the natural route to the heart of the district. Early in the season, when the stage and motor boats forming the chain of communication were operated in a desultory and haphazard way, the lack of system and promptitude could be set down to the newness of the service. There have been eight weeks during which the service could have become regularised, and still it is as irregular and undependable as ever. As a consequence numbers of travellers now are literally "paddling their own canoes", having proved by trial that the public transportation service is not only undependable, but unduly expensive. This service has been subsidised by the Quebec government, which thereby owes it as a duty to the public to see that a proper service is maintained before the subsidy is paid over.

A mining engineer who has just finished a tour of the western part of the gold belt estimates from the evidence he saw that there are about five hundred bona fide prospectors in the district. Provided these were distributed evenly over the whole hundred miles of length, and assuming that the belt is five miles in width, this would put only one prospector on each square mile of ground. The fact is that the larger part of these men are working within comparatively restricted areas, and that only a handful, comparatively speaking, are to be found far from the main travel routes.

It is still much too early in the season to gauge definitely the progress of exploration work in the field. In a number of ways, however, the results during these first eight weeks are rather disappointing. Continued work on the two discoveries under investigation last winter, the Noranda (Powell) and the Hamill option (Cockeram), has failed to disclose any bonanza, but work is being pushed forward steadily with small crews. The claims held by the established mining companies have received comparatively little attention, the rule being a preliminary examination by a party of two or four prospectors. There are no authentic reports of notable discoveries by these parties; but that does not, of course, signify that continued exploration will not disclose payable ore deposits. One property toward the western end of the field, where nine men under the employ of a private syndicate have been working steadily since the break-up, has disclosed a promising find that is being developed as rapidly as this small force can do it. The examination of the old Lake Fortune property has not induced Messrs. MacKay and Alderson to exercise their option on it.

The eastern end of the gold belt, where the Harricanaw river crosses it, contains the most promising of the showings located during the former gold rush. It, too, is being re-examined this season, and we have still to learn the results. Rumours are abroad regarding finds in other parts of the belt, as at Kewagama lake, but all these have still to be substantiated.

For those at work in the woods, midsummer is the season of intense activity, during which is accomplished the solid, systematic work of exploration that precedes most discoveries. The outside world hears little of this work until it results in a find. The autumn is the usual season when such results become known. It still seems likely that the work now in progress will have its reward before the snow flies. The finding of one good mine of even moderate size will repay many times the money expended in the field to date.

$300,000 INVESTMENT IN DANGER

Unless action is taken, and taken promptly, we, the people of Canada, will lose, quite unnecessarily, the benefit of the $300,000 invested in the peat experiments during the last four years. This money has been expended wisely, in a well conceived and cleverly executed series of experiments designed to develop a mechanism that will convert raw peat, containing only 12 per cent. combustible matter, into a high-grade fuel. The engineers directly concerned are satisfied that they have developed a commercially feasible process, and the officers of the Departments of Mines in Toronto and Ottawa are likewise convinced that cheap peat fuel is now available, if we will take the pains to make it. The general public are still, however, almost completely unaware of the truth about the present situation of peat fuel manufacture, and investors still look upon the demonstrated facts and figures as "too good to be true."

"While there may be some doubt as to the results achieved [by the Peat Committee], your Committee is of the opinion that the money expended was justified, and that the Governments interested should consider the advisability of making still further efforts to more fully demonstrate the feasibility or non-feasibility of producing a suitable peat fuel for domestic or industrial purposes, which will compete successfully with other fuels now in use." This is the conclusion of the Senate Committee on Fuel Supply, contained in its final report made on June 25th. The Peat Committee and its work have had much active opposition and numerous detractors, and their evidence has resulted in the Senate Committee's mild expression of doubt. Their conclusion is without doubt — that the work should be carried to a final conclusion.

The Dominion Fuel Board, with full and intimate knowledge of the case, makes the following statement in its interim report: "Too little attention has been directed to the importance of the peat resources Canada possesses. These are very large and are strategically situated in Ontario and Quebec where coal is lacking... Experiments conducted by the Dominion government, and latterly by the Dominion and Ontario governments acting together, at Alfred, Ontario, have produced a high-grade auxiliary fuel... The process evolved is a simple one, consisting of the reduction of the moisture in the raw peat by drying by sun and wind... The Board is of the opinion that peat should be utilized to supply a part of the fuel needs of central Canada, and if the results accomplished last year at Alfred are not sufficient to induce private capital to engage in the production of this fuel, further encouragement should be given the industry by the governments concerned." There is no mistaking the tenor of this statement; the Fuel Board is convinced that the experiments at Alfred have been fully successful, and recommends that further public funds be expended in order to convince the public of the fact.

Last summer 5,000 tons of excellent fuel was made available at Alfred. This summer at least 15,000 tons should have been made there. Through a series of inexcusable blunders, the plant is idle and we shall not get a pound of peat. The responsibility for the bungling is mostly to the account of certain members of the late Ontario government, and need not be discussed here. To retrieve the situation, prompt and decisive action is required on the part of the present Ontario government.

The case of peat fuel as it stands today is briefly as follows: The work of the Peat Committee has apparently been insufficient to induce private capital to invest in a commercial plant, though, to the initiate, the commercial feasibility of the process has been demonstrated conclusively. The coöperative arrangement with the Ontario government once concluded, the Federal Department of Mines cannot logically undertake to aid further, at the expense of the whole Dominion, either of the only two provinces concerned. It therefore devolves upon the provincial governments of Ontario and Quebec to take action.

The Quebec government has offered a bounty, at a rate still to be determined, for peat fuel made in the province. The Ontario government has done nothing to protect its investment.

The idle peat plant at Alfred, Ontario, can be had for the asking by anyone with the means and a *bona fide* intention to operate it; a recent order-in-council passed at Ottawa says so. It is worth $50,000 as it stands, and a moderate sum will change it from the cumbersome steam-driven mechanism it is at present, to the electrically-driven plant the Peat Committee recommend for commercial operation. This plant cannot be moved economically to a bog in Quebec, where it would earn a bounty. If it is to be operated during the season of 1924, active steps must be taken before the snow flies to get it ready.

If private capital should fail to meet this need within the next few weeks, it is clearly incumbent upon the Ontario government to fill the breach. Under the impulse of war-time necessity a Conservative government undertook the experiment. During the last days of the succeeding government, the effort was allowed to lapse. The newly elected Conservative government has professed a keen interest in the mining industry. Here is a chance for it to fulfil these professions in practice, and to complete the task begun in 1919 with the personal support of the present Premier.

NO COMPROMISE WITH COMMUNISM

Last week Hon. James Murdock, Minister of Labour in the Federal government, made a statement that was widely circulated in the public press to the effect that "the representations of the British Empire Steel Corporation had received one hundred per cent. consideration by the Nova Scotia government while the claims of the men had been ignored." Hon. D. A. Cameron, Provincial Secretary of Nova Scotia, one of the ministers thus criticised, has sent a vigorous rejoinder in the form of a telegram in which he points out to Mr. Murdock that the men's side of the case has had continuous attention since February last, when the strike was first threatened. He points out further in connection with the presence of provincial police and militia that "when maintenance men are withdrawn contrary to the regulations of the union, some effort must be made to protect the property, not of the corporation, but of the people of Nova Scotia, who own the mines. The safety of life and property is the only object of the protection afforded and has nothing whatever to do with the claims of the men or the attitude of the corporation."

This statement brings out clearly a point that appears to be little understood either by the strikers at

Sydney or by the general public. The presence of the provincial police and the soldiers in and about Sydney is not due directly to the strike at the steel plant. It is due to the threat of the striking steel workers to wreck that plant. Similarly it is not the walk-out of miners that is the direct cause of the military occupation of the pit-heads, but the avowed intention of the strikers to allow the mines to fill with gas and water, and gradually to be destroyed.

So far as has been disclosed publicly, the provincial police of Nova Scotia and the military authorities now in Sydney have been scrupulous in observing this distinction. They are there to uphold the laws of the land and to prevent the wanton destruction of private property in the steel plant and of public and private property at the mines. They have no function to fulfil as mediators between workmen and their employers. That is the duty of others.

Determined efforts have been made by a number of public officials and others interested to reconcile the views of the contending parties but so far the conferences have been fruitless. Premier Armstrong and Mr. T. J. Brown, Deputy Minister of Mines, have expended their best efforts, and Rev. Clarence MacKinnon, who is a prime favourite with all Cape Bretoners and has been successful in settling several former strikes, has also failed on this occasion. The Lemieux Act is showed up once more as quite useless in settling a serious dispute.

As we pointed out last week, the dispute is virtually between those that uphold the laws of this land, on the one hand, and, on the other hand, those that would, if they could, institute the rule of Communism in Cape Breton and in Canada. It is quite possible that investigation will show that the steel workers and coal miners of Cape Breton have some just causes of complaint against their employers, and these can be adjusted by agreement or compromise; but it would be a crime against our country to comply in any way with the demands made with a view to establishing in Canada the régime that has wrecked Russia.

THE CONFERENCE IN EDMONTON

The gathering of railway operators and coal mine operators now in session in Edmonton under the chairmanship of Mr. A. C. Magrath is the first occasion on which those with the problem of "Alberta coal for Ontario" on their hands have come together in formal conference. Hitherto the negotiations have been of rather a long-distance variety, which may be responsible for the lack of satisfactory results. Now that there is a prospect of miners and railway men attacking the problem in concert, we may look forward to a genuine decision.

As we said when Sir Henry Thornton first announced the $9.00 rate on coal from Alberta to Ontario, we consider that this is merely a "feeler". Likewise the contention of the Alberta miners that it will cost them $4.50 a ton to put their coal on the cars contains something in the nature of a bluff.

If direct negotiations of this sort should disclose the fact that Alberta coal cannot be shipped profitably to Ontario, then the sooner we know it the better it will be for all concerned. Until the point is settled definitely and all those concerned are convinced the scheme is impracticable, there is bound to be a good deal of restlessness and dissatisfaction in various quarters. If the Alberta mines are not to have this opening for a market, they should know it as soon as possible. If the people of Toronto must continue to import coal from the United States, their contracts there should not be subjected to the doubt of an alternative Canadian supply. We trust the conference will result in a definite decision. We still hope this decision will allow the shipment of Alberta coal to Ontario.

A PROSPECTOR'S MONOLOGUE

They say our lives are lonely, pard,
That our hardships are severe;
But they do not know the pleasures
We enjoy while camping here
On this lovely pine-clad mountain,
Where the air is soft and sweet,
With the snowy peaks above us,
And the valley at our feet.

We can hear the grouse a-drumming
As we sit around the fire,
And the humming-birds are humming
On bright wings that never tire.
All around us happy families,
Birds and beasts so full of fun,
Till the "savage" from the city
Comes amongst them with his gun.

They say we hear no music —
When the woods are full of song;
Why, each bird's a prima-donna —
Never sings a note that's wrong.
And the wind above the pine-trees
Harps his way the leaves among;
Never was a grander chorus
Than when Spring-time comes along.

They think we see no pictures —
When we see them every day;
Not in galleries, on canvas,
But in Nature's grander way;
Painted not by ancient "Masters",
Nor by "Moderns", great or small,
But by Nature's mighty Artist
Greatest "Master" of them all.

DONALD C. SIMPSON.

Natural Gas and Petroleum Resources of Western Canada

III. — The Irma-Fabyan-Wainwright Gas Field

By NEWTON W. EMMENS

The striking of a big flow of natural gas in the initial well of British Petroleums Co. (Canada) Limited, in Sec. 36 of Tp. 45 N, R 7 W of the 4th Meridian, of east central Alberta seems to prove the existence of an extensive gas field in the Irma-Fabyan-Wainwright section, having a length in a northeasterly direction of at least eleven miles and of unknown width. In this eleven miles three wells have been drilled, two by the Imperial Oil Company and one by British Petroleums. The most southerly is in Sec. 4, Tp. 45, R 8 W, the second in Sec. 18, Tp. 45, R 7 W and the most northerly in Sec. 36 of the same township, as above stated. All these wells struck big gas flows, with some oil showings. It is interesting to note that the wells are along a line that is approximately 45° east of north, which coincides with the "45 degree line" so dear to the hearts of the Appalachian oil men and regarded by them as an exceedingly favorable indication of a productive field. However, it is too early yet to state that this is the real direction of the longest axis of the field, as development has not progressed far enough to enable a definite conclusion to be arrived at in this respect. It is believed that oil will be found in commercial quantities below the gas sand, to prove which British Petroleums Limited is preparing to drill another well about five hundred feet southeast of their No. 1, well using the gas from this latter as fuel.

The Imperial Oil Co. is rigging up to drill another well on Sec. 14 of Tp. 45, R 8 W of the 4th Meridian, just south of the Canadian National Railway bridge over the Battle river west of Fabyan station, and about midway between their other two wells.

Gasoline and Carbon Black from Gas

In this part of Alberta, as there is no immediate market for natural gas for domestic and power purposes, it has been deemed advisable to carry out an investigation into the nature of the gas with a view to its utilization for the production of gasoline and carbon-black. So far as this investigation has gone the results are very satisfactory, as it has been found that the gas can be profitably utilized for these purposes.

The use of natural gas for the manufacture of carbon-black has been, and is, of the greatest importance where the field from which it is obtained is situate at too great a distance from the large centres of population for other uses, and has been the means of turning more than one enterprise from a failure to a success. The Monroe field of Louisiana is a notable example of this. A few years ago several wells were drilled in the Monroe field in an unsuccessful search for oil. Although they disclosed a considerable flow of gas, they were so remote from large centres where this gas would be in demand for domestic or power purposes, that the wells were capped and the field allowed to lie dormant. When the demand for gasoline and carbon-black became so urgent during the war, this Monroe gas was tested and found to contain from one to two pints (Imperial) of gasoline per thousand cubic feet of gas, and in addition the residual gas yielded eight-tenths of a pound of carbon-black per thousand cubic feet of gas burned. Since then the Monroe field has been systematically developed and produces large amounts of both gasoline and carbon-black from this gas.

Uses of Carbon Black

In the United States the production of carbon-black is an important industry with an annual production of about fifty million pounds, in the manufacture of which some forty-one million cubic feet of natural gas are consumed. Carbon-black is a velvety pigment with a brilliancy and intensity of color equalled by no other black. Its chief use is in the rubber industry, both as a coloring material and as a filler. In the manufacture of automobile tires it also acts as a reinforcing agent, as it has been found that by the addition of carbon-black to the rubber the tire has a greater mileage and a better traction because of the increase in tensile strength and elasticity due to its use.

In the printing trade carbon-black is used in the preparation of printer's ink because it possesses properties that are especially adapted to its needs. When mixed with oil and other chemicals it has remarkable covering power, makes an instantaneous and legible impression, drys rapidly so as to allow the presses to work at a high speed, and has the fine black color so necessary for this work.

Carbon-black is also used in the paint trade and in the manufacture of black varnishes and enamels, where its high coloring properties and great covering power are unsurpassed. Smaller quantities are also used in the manufacture of phonograph records, shoe and stove polish, carbon paper, typewriter ribbons, black leather, drawing and marking inks, buttons, celluloid, electric insulators, and many other articles where the use of an intense black coloring matter is required.

Not only is there a good domestic market for carbon black, but there is a growing export trade. The market value is based on the quality of the product and the available supply compared with the demand. At the present time there is a scarcity of carbon-black and the price ranges from 17 to 50 cents per pound, the higher prices being paid for the finer ink-making grades.

Natural-Gasoline from Gas

The extraction of gasoline from natural gas owes its present large proportions to the great demand for gasoline by automobiles, trucks, tractors, motor boats and gasoline engines used for all sorts of power-purposes; and were it not for this natural-gasoline (as the gasoline extracted from natural gas is called to distinguish it from the gasoline made by distilling crude oil) the users of this useful petroleum product would be paying a much higher price than they now do, if indeed sufficient could be produced by the refining and cracking of crude oil to supply the demand. The importance of the natural-gasoline industry can be better appreciated when it is understood that hundreds of millions of gallons of gasoline are recovered annually from natural gas. In the United States the annual production has a cash value of tens of millions of dollars, and this huge sum goes to the producers of natural gas who have equipped their properties with the requisite plants, or to gasoline extraction companies who buy the gas from the lease

owners at a fixed price per thousand cubic feet, extract the gasoline and either sell the residual gas for commercial purpose or manufacture carbon-black from it.

Analysis of the Gas

Gas fields in which there is practically no market for tht gas as such — that is for domestic and power purposes — and which are within a reasonable distance of transportation, as are the gas fields of southern and eastern Alberta, afford a splendid opportunity for the building up of profitable enterprises by the extraction of the gasoline contained in the gas and the manufacture of carbon-black from the residue, provided always, of course, that the gas contains sufficient of the hydrocarbons, other than methane, necessary for such purposes. Their content of these hydrocarbons can be easily determined by an examination of the gas.

The examination and testing of natural gas for its gasoline content requires special knowledge and has proved a stumbling block to analysts who have not had practical experience in this class of work. The ordinary laboratory explosion method of determining the methane, ethane and higher hydrocarbons in natural gas is of little value in arriving at its gasoline content, for the reason that it gives only the two predominating hydrocarbons and does not give the quantity of gasoline vapor; also a very slight error in manipulation is multiplied many times when calculating the results of the analysis to a percentage basis, and the relation between the volume of carbon dioxide and the contraction produced by combustion may indicate the presence of hydrogen, although the sample being examined may be entirely free from that gas. This work should, therefore, be done by an analyst or petroleum engineer who has not only the technical training but also practical experience in this class of work, and preferably by one who has also had experience in the building and operating of plants for the recovery of gasoline from natural gas, because the gas is not uniform and not only varies in gasoline content as between wells (even when the source of the gas is the same), but from day to day from the same well.

Practical Tests

The preliminary examination of the gas is usually made by the specific gravity and the oil absorption methods, which are reliable guides as to the gasoline contained in natural gas, provided the tests are properly made. They will, however, lead to erroneous conclusions if made by those who have not had considerable experience in this work. If the results of such a preliminary examination show that gasoline vapor is present in the gas in sufficient quantity to make its recovery profitable, the next step is to make a series of field tests at the wells in which a measured quantity of the gas is passed through an apparatus that actually extracts the gasoline under conditions as nearly like those of the commercial plant as possible. These tests are required for the determination of the type of plant best suited to treat the particular gas under examinaion, because gas, like metallic ores, has peculiarities of its own that must be take into consideration in the design of a plant to get the highest efficiency.

The examination of the gas, afer the gasoline has been extracted, for the manufacture of carbon black can be made by analysis and by calculating the amount of carbon-black it will produce, or the gas can be tested in the field by actual combustion in a suitable apparatus, in which event a measured quantity of gas is passed through the apparatus and the carbon-black recovered and weighed. The writer prefers the latter method.

PETROLEUM PARAGRAPHS

The Illinois-Alberta Oil & Refining Co., is constructing a gasoline plant to treat the gas from their wells in sec. 12 Tp. 20 R 3 W of 5th Meridian. This gas is reported to yield two gallons per thousand cubic feet.

The work of laying the pipe-line from the Viking gas field to the city of Edmonton has commenced and it is hoped that the line will be completed this winter. All the necessary pipe, consisting of approximately 40 miles of 12-inch and 38 miles of 10-inch, has been bought and part of it delivered. There have also been purchased four ditching machines for digging the trenches in which to lay the pipe.

South of Taber, Alberta, in Tp. 9 and 10, R 16 west of the 4th Meridian, two wells are being drilled by the Canadian Western Natural Gas Co. for gas. This company drilled in a good gas well late last fall, but the water came in and efforts to shut it off have proved unsuccessful. It is expected that the new wells will be free from this water trouble.

South of Monitor, in Eastern Alberta, the West Regent Oil & Gas Co., has resumed drilling in Section 19, Tp. 34, R 4 W of the 4th Meridian. This hole had been previously drilled to a depth of 3,300 feet and shows both oil and gas. It is expected that much greater pro duction will be obtained by drilling deeper.

In the Sweetgrass section of southern Alberta slow progress is being made on several wells. Coutts-Sweetgrass Oils Ltd. are setting casing to shut off the water in their well in Sec. 1, Tp. 1, R 15 W of the 4th Meridian. Border Oil Ltd. are drilling in Sec. 6 Tp. 1, R 14 W of the 4th Meridian and are down some 2,300 feet. The Boundary Oil Co. is drilling in Sec. 3, Tp. 1, R 15 W of the 4th Meridian at a depth of 400 feet. The Moodie Syndicate is drilling in the same township, Sec. 4, at a depth of 350 feet and the Canadian Oil & Refining Co. is making slow headway with their test at a depth of 1,600 feet in Sec. 29, Tp. 1, R 11 W, of the 4th Meridian.

PERSONAL AND GENERAL

Dr. J. A. Bancroft and Mr. E. J. Conway, associated with the Granby Consolidated Mining & Smelting Co. as geologist and field engineer respectively, are in the North inspecting the Sunshine and George groups, which are under bond to the Company. The former is on Glacier Creek, and the latter on the Bear River.

Mr. H. S. Munroe, general manager of the Granby Co., and Mrs. Munroe, Col. Crabbs, of New York, President of the Company and Dr. Probert, Dean of Mining at the University of California, passed through Stewart recently and, after a short stay in the Portland Canal District, returned to Anyox, the Pacific Coast headquarters of the Company.

Dr. W. E. Cockfield is now in the Mayo silver district, having spent the latter part of May and the first part of June in the Whitehorse district. The survey of the latter area he has left in charge of Mr. A. H. Bell.

Dr. T. O. Bosworth has recently returned to London from Canada, where he has conducted certain investigations affecting British petroleum interests,

The Quebec Asbestos Industry

II. — Efficiency in the Milling of Asbestos

By G. ERNEST BOOKER

The fact that the milling of asbestos is to a large extent inefficiently carried out naturally leads one to search for improvements that will either increase the overall efficiency to the greatest extent, as in the case of a new mill, or will enable one to make such changes in an existing mill that the losses at present taking place are considerably reduced. The first consideration must therefore be the grouping of all the essential features an efficient mill should include. As a full discussion of the details to be considered under the various groups is beyond the scope of this article, it will be sufficient to note the headings of the several groups:

(1) Economical milling efficiency
(2) Mechanical and thermal efficiency
(3) Reliability and continuous operation
(4) Accessibility
(5) Labor and its welfare.

While the factors that enter into the general design and layout of a mill are too numerous to mention, they may all be classified under the above heads. The value of each detail under any heading has not only to be considered in one phase only, but also in its bearing and value in relation to the other groups, thereby co-ordinating each and every process or operation into a complete unit.

Design of a 1,000-ton Mill

These details will, of course, vary in every case, and as it is impossible to designate fixed values for particular points or features, it will be as well to take as an example the preliminary plans of a 1,000-ton mill recently designed.

The flow sheet (fig. 1.) is self-explanatory, and while it is very similar to some existing mill flow sheets, the addition of both a mechanical and an electrical dust treating plant is perhaps worth attention.

The question of dust treatment for the recovery of fibre at present lost is a vital one and results can be achieved in any of the following ways:

(1) By settling in a dust chamber
(2) By electrical precipitation
(3) By combined mechanical separation and settling.

Full details of this dust and fibre recovery problem will be dealt with later. In this case, however, we have the second and third methods of dust treatment included. The object in view is to recover the longer and more valuable grades of fibre from the dust passing through the mechanical unit before the general precipitation takes place, thereby ensuring a maximum extraction and minimum loss.

Details of Flow Sheet

The preliminary plans of the mill (Fig. 2.) may be briefly described with advantage. The rock bin is fed directly from the mine by an automatic skip, and leaves the bin on a 12" grizzley, all oversize material going through the primary crusher before joining the undersize and passing through the secondary crushers. From here it is fed into the dryers and in due course passes into the primary separators. It will be noted that up to this point gravity has been the sole conveying medium.

The rock leaving the primary separators is then carried by an inclined conveyor to the feeders supplying the secondary separators, the tailings from which descend by means of a chute to the tailings conveyor which deposits them upon the dump. The fibre from all sources goes through a series of cleaners and graders to the bagging machines from which it is carried by means of the shipping conveyor directly to the freight cars or taken into storage as desired.

Treatment of Dust

The dust collected from all sources is first led into the mechanical dust separator, which extracts all of the longer fibres that are carried along with it, the balance going into the electrical precipitator which precipitates all the remaining solid matter.

It might be mentioned in passing that the dryers are of the Straight Flow type, and oil fired. The advantages of oil as a fuel are well known and it is expected that the increased cleanliness and freedom from sooty deposits in addition to the flexible temperature control will prove highly economical and also will produce cleaner fibre.

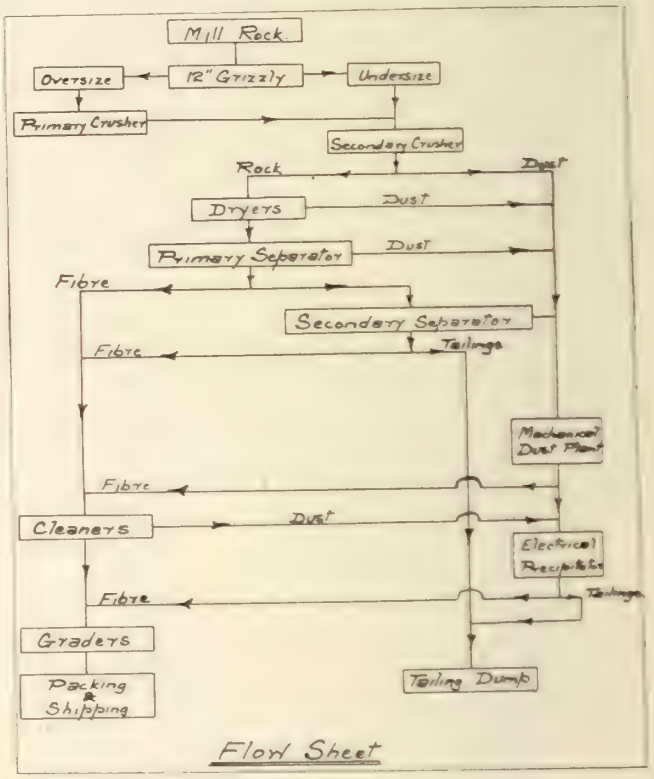

Fig. 1.

Concrete Construction Best

The type of construction used for the mill building and rock bin is probably the greatest change from present practice. The vibration usually found in any milling process has always been a source of trouble and probably will be until efforts are made to neutralize its effects. In the old type of timber framed mill building the vibration actually originating at the machines becomes magnified considerably and the resultant vibration is frequently so great that not only is the maintenance and wear on the machines excessive, but it also results in the ultimate destruction of the building itself.

The monolithic concrete building of which this particular design is an example tends to nullify the vibration of the machinery and thereby to eliminate the cause of much expense and loss in maintenance and replacement.

Other points that increase the desirability of the monolithic concrete building are the fire and weather resisting

qualities, the increased lighting and improved working conditions. It has been proved that not only do proper lighting and reduced vibration increase the efficiency of the mill hands, but also that the elimination of dust and generally improved working conditions show beneficial results in the relations between employers and employees, as well as greater production.

The cost of construction today of reinforced concrete buildings is almost identical with that of similar timber framed buildings.

Fibre Moves Continuously from Crushers to Bagging Machine

Another point that may be mentioned is the arrangement of the equipment. The fibre from the time it is separated from the rock is not allowed to rest until it is in the bagging machines. This is a radical change from the all too common practice of moving fibre at a high velocity through a part of the mill, then bringing it to a standstill at another point only to expend more power and energy in helping it through the remainder of its travels. It will be seen that the actual distance travelled by material through the mill and the power absorbed in elevating and conveying has been reduced to a minimum, the actual distance in this case being about 300 feet, the vertical component of which is only about ten per cent.

Re-Modeling Old Mills

Turning to the question the efficiency of existing mills, the matter resolves itself into three problems; first, the location of all present losses; secondly the proper application of remedies to prevent the recurrence of such losses;

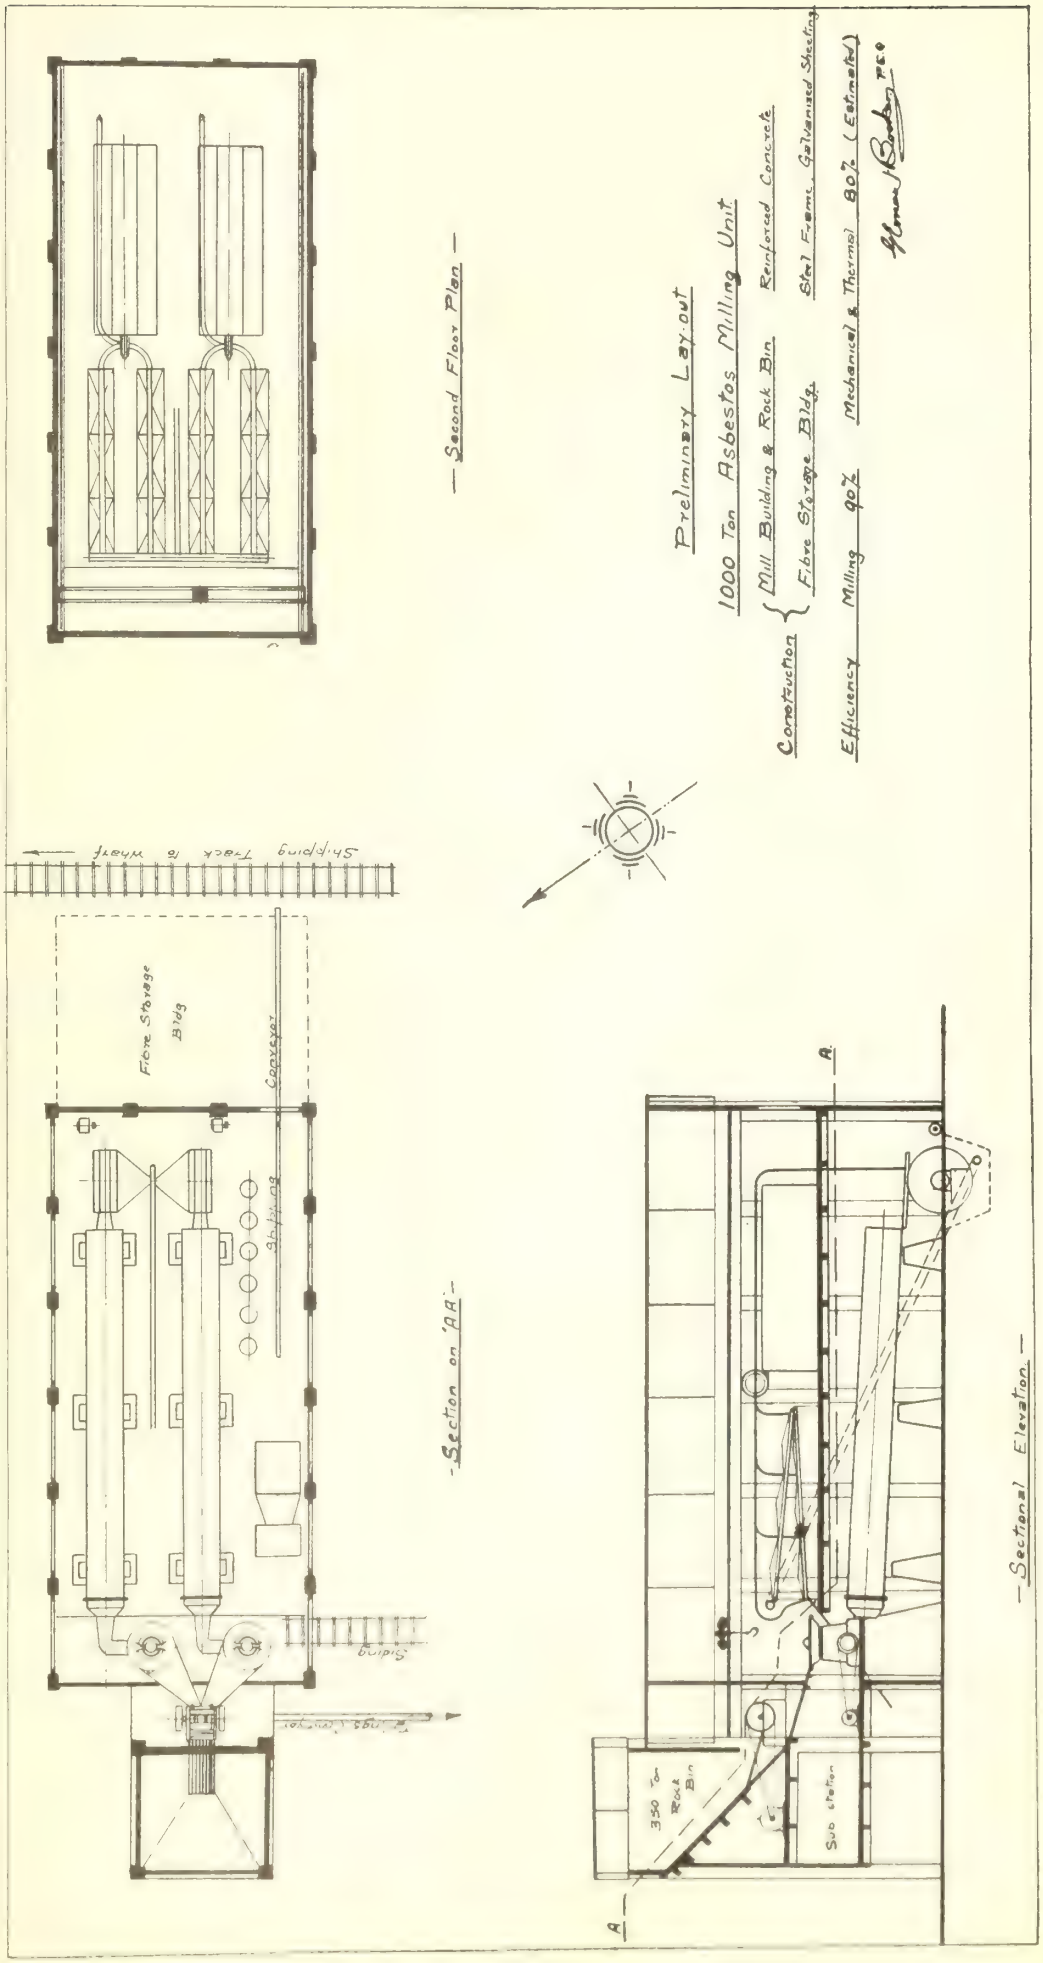

Fig. 2.

and thirdly, the most suitable means of recovering, grading and handling the additional fibre in the dust at present lost. The first point naturally calls for a thorough examination of all the equipment in the mill under consideration. This achieved, the necessary changes and replacements are of a simple nature in many cases and can be carried out by the mill crew, or the millwright gang.

The choice of a type of dust treating and fibre recovery plant is, however, so much dependent upon the actual conditions prevailing, that the possibilities of each type, its advantages and disadvantages, must all be carefully considered for each case. The problem is one of prime interest, and when the possibilities of each type of treatment are described it will be as well to attempt to determine whether or not dust or fibre-laden air is similar in its behavior to a colloid, which is a fluid containing solids in permanent suspension.

MACKENZIE RIVER MAPS

The Mackenzie river, the largest of all Canada's water systems, does not present to the traveller today the difficulties and dangers of former times. Tapped by railways at two points and traversed by up-to-date steamers, the waterways of which this river forms a principal part may be travelled to the delta of the Arctic ocean in all the comfort and security that attends inland water transportation.

With the increase in interest in this district that has been brought about by recent oil and other mineral discoveries, as well as from the general enlightenment regarding it that has seemed to pervade the older parts of Canada in the past few years, the need for accurate and authentic information in the matter of surveys has been felt. To meet this need, surveys have been carried on by the Topographical Survey of Canada, Department of the Interior, along the main waterways of the district, since 1921 and are being continued this year.

As a result of these surveys, a series of thirteen maps of this district has been issued embracing besides a general large scale map of the entire area, detailed maps of the lower Athabaska and Slave rivers, Lake Athabaska, Great Slave Lake and the Mackenzie river They are printed in three colours, each map being 24 inches by 34 inches in size. In addition to the outline of the waterways themselves, they show all islands and shoals, the navigation routes usually followed, magnetic variation at various points, the positions of the survey monuments erected and in general all known information relating to the topography of the country.

The maps are divided into series "A" and series "B", issued in separate covers. Series "A" includes besides the general map on a scale of fifty miles to an inch, two maps on a scale of four miles to an inch and one on a scale of six miles to an inch. The first two take in the districts respectively from McMurray to Chipewyan and from Chipewyan to Fort Smith. The third is of lake Athabaska. Series "B" includes, also besides the the general map, nine maps, eight of which take in the districts respectively from Fort Smith to Resolution, Resolution to Fort Reliance, Resolution to Windy Point, Providence to Simpson, Simpson to Wrigley, Wrigley to Norman, Norman to Hume river, Hume river to Thunder river including Good Hope, and from Thunder river to McPherson. Those of the latter series are on a scale of four miles to an inch with the exception of the second one mentioned, which is on a scale of six miles to an inch.

Single copies of these maps or the complete set may be obtained free of cost from the Surveyor General, Ottawa. Additional copies may be obtained at twenty-five cents for individual maps or seventy-five cents for series "A" and two dollars for series "B".

BLUE SKY LAWS FOR CANADA

The *Financial Times* of Montreal has been actively interested during recent months in the question of a "Blue Sky" law for the province of Quebec. In the issue of July 14th it sums up the present situation as follows:

"When Quebec Province, with its conservative tendencies in legislation, is giving serious consideration to a Blue Sky law, it seems clear that behind it rests a more or less widespread demand among some sane financial houses.

"Blue Sky laws are very much like free trade — ideal in theory but rather difficult in practice. The danger that has been found to result in the past has been that the authorization of a public issue under provincial or State regulations, has been assumed to carry with it a guarantee as to the desirability of such an issue as an investment. It has been looked upon almost in the light of a Government bond. So much so that the Province of New Brunswick has taken care to have a special note appended, warning intending investors that authority to sell securities is in no sense to be regarded as a testimonial of their merits.

"Probably the strongest features of such legislation arises from the enforced publicity through information that must be filed with the central authorities. This stops some crooks. Then the licensing of salesmen as well as firms has been found beneficial. It is a little harder to fleece the unwary, particularly for outside salesmen with fake schemes who swoop down upon a district and then disappear with the savings of the public.

"The legislation for the Province of Quebec should enforce fuller information in the prospectus as a protection to investors against that type of promoter who is unloading at an excessive price upon the public. Then there should be some penalty, easily enforced, against the firm or salesman who are parties to fraud.

"Many Blue Sky Acts are satisfied with the cancellation of the license. But this is not enough. Apart from outside propositions — including scores of those oil prospectuses that have taken millions out of small investors — the type of issue that seems likely to call for most careful supervision is the mining stock. A rush of these is probable in the new gold area of Quebec. The Blue Sky law should make it impossible for owners of claims and promoters to absorb the whole of the proceeds. A new mine is ordinarily a gamble: the large proportion of the funds available must be expended in development work; otherwise the investor has no chance to win out.

"The Blue Sky legislation of Quebec, with careful handling, can be made of material benefit, not only to the investor, but to the better class of financial houses who will welcome better legal protection against unscrupulous and irresponsible transactions.

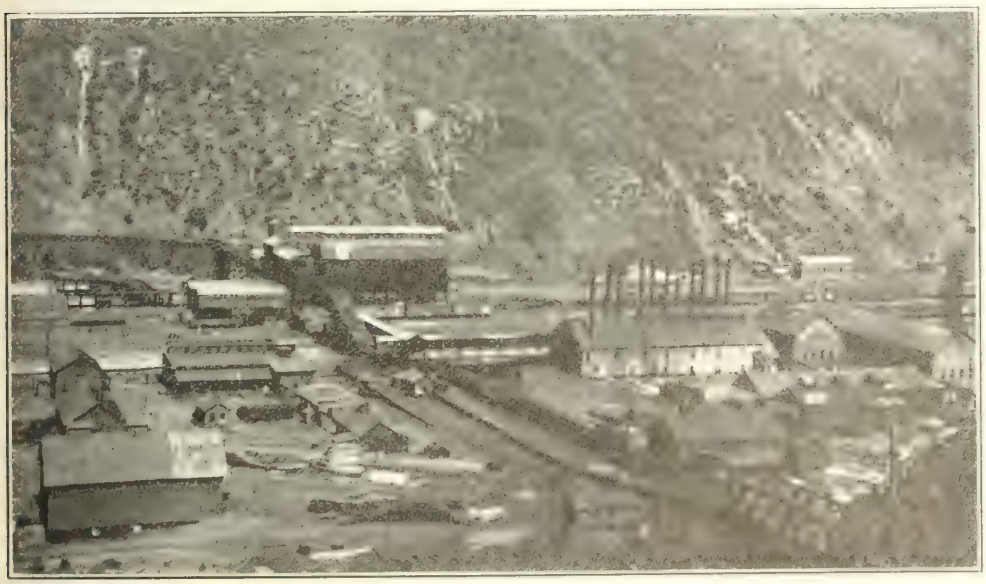
Molybdenite and graphite are very much alike, but molybdenite is blue-black, while graphite is gray-black. When the marks made on rough porcelain are compared, the molybdenite shows a greenish tint, while the graphite mark is pure gray; this difference can be seen when the marks are made on paper and rubbed until they are spread out thin.

The Collieries of British Columbia

II. — Michel and Corbin

By ROBERT DUNN

The Coal Creek collieries are under the management of Bernard Caufield, who, in common with Mr. Wilson, the President of the Company, has faced for years the problem of mining coal under exceptional conditions. George S. Rice of the United States Bureau of Mines, as a result of an investigation following a disastrous "bump" in November, 1916, reported that the Coal Creek coal beds were very gassy, and that their exploitation presented unusual natural difficulties because the beds are at the base of elevated plateaus and it is impossible to reach the coal except through the outcrop, and also for the reason that the coal is under such a heavy load that it requires great care in mining to prevent squeezes and "bumps". Mr. Rice stated that these "bumps" are believed to be caused by the subsidence of the roof in certain areas under rigid rocks, leaving a great unsupported span of rock strata. "When one of these has given away" he said, "it means the hammer-like blow of thousands of tons of rock striking on the immediate roof or flexible stratum overlying the mine, which imparts the blow downward, breaking timber, causing extensive falls in the mine and sending rock tremors through the strata." At that time Mr. Rice made a number of important recommendations, which were followed up by others from time to time by officials of the Provincial Mines Department, all having in view the promotion of safety in the underground workings of these mines. These regulations have been faithfully adhered to by the company. There has been a regular and rigid inspection by Robert Strachan, the Senior Inspector of Mines, and as a result of these combined efforts conditions have, without a doubt, very materially improved in recent years.



Michel Colliery, Michel, B.C.

Michel Colliery

The Michel Colliery of the same Company, Robert Bonar, Manager, is situated on both sides of Michel Creek and is connected by rail both with the Canadian Pacific and Great Northern Railways. There are three mines, No. 8, No. 3 and No. 3 East, but during the past year practically all production has come from the first two mentioned. In No. 3 East the work has consisted chiefly in the developing of a new seam in No. 16 East Level off the main slope and in general repairs to the roadway.

The general method of work is pillar and stall in all the mines, pillars being extracted in certain portions of No. 3 East and No. 8 mines. Haulage is by horse from the working-faces to the partings, from which the loaded cars are taken to the tipple by means of gravity-inclines, main and endless-rope haulage, and compressed-air locomotives.

As No. 8 mine is at an elevation of 500 feet above the tipple, the loaded cars from this mine are weighed at the top of the incline, where the coal is dumped into bunkers, then loaded into skips and lowered by gravity, and again dumped into other bunkers situated at the bottom of the incline, where it is loaded into mine-cars, these being conveyed to the tipple by endless-rope haulage.

The Tipple

A steel tipple, 664 feet in length and 14 feet in width, extends right across the valley and receives coal on both sides; the loaded cars from the south side are weighed at the foot of the tipple incline, up which they are taken by a Green car-haul consisting of an endless chain that travels on car-wheels, the latter acting as pushers or retarders of the mine-cars on the incline. The track for the mine-cars is laid inside that on which the pusher-wheels run, and when a car is delivered at the bottom of the incline the pusher-wheels move in behind, gripping the rear wheels of the car, thereby conveying the loaded cars up to the dump on the tipple.

This dump is a continuation of the track, with a pitch increasing from 20 to 60 deg. and when the car reaches this pitch the door opens, discharging the coal into the dump, the chain-haul continuing to travel round a large sprocket-wheel, conveying the car to the overhead track and then back down the incline. On the No. 8 side of the tipple the cars are dumped by an automatic dump and returned by a trimmer underneath the track to the endless-rope haulage, which conveys

them back to the bunkers at the bottom of No. 8 incline. The tipple is equipped with shaking screens and picking-tables, the slack being conveyed by a travelling belt to the slack-bins, from which it is drawn into cars and conveyed by steam-locomotive to the coke-ovens. The tipple machinery is driven by electric power, provision being made for loading open and box cars, the latter being handled by two Smith gravity box-car loaders,

Surface Plant

The boiler-plant consists of eleven boilers having a total capacity of 1,650 horse-power, and along with the engines are housed in a fire- proof brick building. Power to drive the underground hoists and pumps is provided by two compressors — one of the Walker, the other of the Rand type — having a total capacity of 8,000 cubic feet of free air a minute, compressing it to 100 lb. to the square inch. Power to drive the air-locomotives is provided by a high-pressure Rand compressor having a capacity of 1,450 cubic feet of free air a minute compressing it to 1,200 lbs. to the square inch.

The electric plant consists of two 250-kw. generators, which provide the power for the tipple machinery and lighting purposes around the colliery and the town of Michel.

A well-equipped lamp-room is situated in a central position at the mines, where the electric head-lamps used by the workmen and the Wolf safety-lamps used by the officials for testing purposes are cleaned and repaired. There are in use at the present time 345 electric head-lamps of the Edison type and twenty Wolf safety-lamps, while Burrell gas-detectors are provided to enable the detection of lower percentages than could be detected by the ordinary safety-lamp.

Large stables are provided for the forty horses employed in and around the mines; those employed underground are brought out at the end of shift. A large wash and change room is located convenient to the mines where each employee has his own locker (of steel construction) and provides his own soap and towel. Well-equipped machine, blacksmith, car, and repair shops are located in a central position at the colliery.

Mine No. 3, M. Littler, overman, operates on the upper No. 3 seam and is reached by a crosscut tunnel from the surface, which intersects Nos. 5, 4, 3 and upper No. 3 seams, only the last being mined. A Sullivan fan, 12 x 6 ft., delivers 104,870 cubic feet of air a minute. No. 3 East Mine, M. McLean, overman, is situated about half a mile east of the tipple and is ventilated by a 16 x 8 ft. Wilson fan giving 97,600 cubic feet of air per minute. No. 8 Mine, A. Howden, overman, is on the north side of the valley and operates the upper portion of the No. 8 seam. It is ventilated by a compressed air driven 8 x 4 ft. Murphy fan with a per minute capacity of 43,800 cubic feet of air.

The Corbin Collieries

The Corbin Coal & Coke Co., Rush Taggart, New York, President; R. S. Ord, Spokane, Washington, General Manager; and E. L. Warburton, Corbin, Mine Manager, is 14 miles from McGillivray Junction on the Crow's Nest Branch of the Canadian Pacific Railway. It is reached by means of a branch line called the Eastern British Columbia Railway and consists of Nos. 4, 5 and 6 mines. All the output for 1922, however, came from Nos. 4 and 6 mines. No. 3, or the "Opencut", where the conditions were such that the coal was simply shoveled from the outcrop into waiting cars, has not been worked recently. In 1921 the plant was dismantled.

The surface equipment may be briefly described as follows: The boiler plant, consisting of two Jenckes return-tubular boilers and one of the locomotive type, has a total capacity of 275 horse-power. The electric plant consists of one 70 horse-power generator, alternating type, 2,300 volts, driven by one 100 horse-power steam-engine, and provides the power to drive the motors at the machine-shops, the fan at No. 6 mine, and for lighting purposes around the town of Corbin.

The tipple, constructed of wood, has a bunker capacity of 1,200 tons and is equipped with a Marcus screen and conveyor-belt, driven by a 60 horse-power steam-engine. A lamp-room is located in a central position at the mines, where all safety lamps are cleaned and repaired.

The lamps in use are chiefly the Edison electric type, the remainder being the Wolf safety, the latter being used by the officials for testing purposes, while a Burrell gas-detector is provided for the detection of lower percentages of methane in the mine-air than can ordinarily be detected by the Wolf safety-lamp.

No. 4 Mine is operated on No. 4 seam, the bulk of the coal being produced from the 400 and 500-ft. levels, where the pillars are extracted by the caving system on the retreat. W. Almond is the overman. No trouble has been experienced recently with fire, which has been a difficulty in the past, there being an area sealed off in the 400-ft. level for this reason. No. 5 Mine did not produce last year but a considerable amount of development was done in No. 6, where three separate districts have been opened up and are in a position to produce. Only the lower seam, which is about 40 ft. thick between walls, now is being operated. It is being blocked out on the double stall method, pillars between levels measuring 70 x 120 ft. A small Sirocco fan provides ventilation.

No. 4 Mine, Corbin, B.C.

Production for 1922

The total output of the coal mines of the Crow's Nest field for last year was 554,361 tons, as compared with 759,755 tons for 1921. While this shows a decline it is to be remembered that the mines were shut down for almost five months as a result of a dispute as to wages. This fully accounts for the falling-off of production. Up to the present this year there have been no interruptions and, although there is no doubt that the Fordney

tariff is having its effect on exports, the coal of this district appears to be finding a profitable market. There are indications that it is invading with success some parts of the Canadian prairie market, and, as it is a splendid domestic fuel comparing more than favorably with most of that of the Province of Alberta, there is no reason to doubt that it is destined to attain greater popularity among the consumers of the provinces of Saskatchewan and Manitoba.

(To be continued)

LOW-TEMPERATURE CARBONIZATION OF COAL

Description of 400-ton Plant now under Construction at Walkerville

The 400-ton carbonization plant now under construction by the Ford Motor Co. of Canada at Walkerville, Ontario, is described in an article by V. Z. Caracristi in *Power* for May 29th, 1923. Mr. Caracristi and his associate Emil Piron, who had previously specialized in high-temperature coke oven practice, two years ago tackled the problem of designing a practical apparatus for the low-temperature distillation of coal, and after a series of laboratory experiments and the erection and operation of a small experimental unit of 25 tons daily capacity at Huntington, West Virginia, completed the design of the plant being built at Walkerville. Mr. Henry Ford has supported this enterprise from its inception.

An effective carbonization plant has been the object of scores of researchers and half a dozen governments during the last decade. By this means fuels at present regarded as low grade can be made to produce high-grade fuel as well as eminently useful by-products. "At present there is no commercial advantage in distilling at low temperatures such coals as give metallurgical coke, because of the great value of such coke. Low-temperature carbonization can be most advantageously applied, however, to coals and lignites that do not yield good metallurgical coke but will provide a material that can be mixed with coal containing the resins necessary for agglomeration into coke, in proportion to the amount of such resins available, the resulting product being a metallurgical coke of high quality... The greater part of fuel available for power plant and gas-making purposes is high volatile coal. The efficiencies obtained in the conversion of this fuel into steam and gas have reached a point where the field for improvement is practically negligible. This has been clearly realized not only by individuals but by public bodies and governments, and a vast amount of energy has been expended in an effort to extract from this fuel, before its destructive combustion, a number of valuable products."

The New Oven

The oven designed by Messrs. Caracristi and Piron uses the same essential ideas as that used to make by-product coke, adapted to meet the special requirements of low-temperature carbonizing. The principal novel feature is that the fuel, crushed to pass a half-inch ring, is fed in a horizontal layer one-half inch thick on a conveyor 9 feet wide, which passes through the length of the oven, 40 feet, in five minutes, when the coal is thoroughly carbonised (10 to 15 per cent. volatile remaining) and drops off the conveyor. The problem of supplying heat effectively to this thin layer of coal has been solved in a very ingenious way. The conveyor is made of interlocking segments of cast iron, which floats in a shallow bath of molten lead. The hearth that holds this lead is composed principally of cast iron U-shaped tubes placed side by side, the legs projecting upward into combustion and exhaust chambers on either side, these chambers being separated from the distillation chamber in the centre by curtain walls of fire brick. The walls of these tubes or flues, the melted lead above and the iron plates of the conveyor constitute a metallic conductor whose efficiency is almost perfect. It is the low efficiency in conduction of the partition walls between coal and fuel gas that has frustrated most former attempts to design an effective low-temperature carbonization oven.

The new oven makes use of the usual regenerators to conserve heat, and likewise uses the heat of the prepared coal by returning it, with the coal conveyor, on a separate coke conveyor beneath the oven. The coke needs no quenching on being discharged from this coke conveyor, which is sufficient demonstration that little heat is lost at this end of the operation. With proper insulation, it is calculated that the operation will consume 560 B.t.u. per pound of coal treated, allowing 80 per cent. efficiency for the apparatus as a medium for the transfer of heat. "Assuming that the coal has 13,000 B.t.u. as received, the heat losses will be 4.3 per cent., and the thermal efficiency of the process will be 95.7. In view of the ordinary daily operation of high-temperature coking plants, where a heat efficiency of 92 per cent. is not unusual, this figure will balance correctly with accepted data."

The Products

The distillation is effected at a temperature of 1200° F. The fuel obtained is of a coke-like character, high in carbon, with not more than 15 per cent. volatile, which will burn without smoke and can be used: (1) "to be briquetted into a smokeless domestic fuel of anthracite character; (2) to be pulverized and burned directly in furnaces; (3) to be burned directly on chain-grate stokers; (4) to be ground and mixed with high-volatile coal for the purpose of making metallurgical coke." The by-products, per ton of coal, are: (1) "8,000 to 7,000 cu. ft. of 600-700 B.t.u. gas; (2) 5 gal. motor fuel directly stripped from the gas; (3) ammonia corresponding to 20 lb. of ammonium sulphate stripped from the gas and condensation liquor; (4) 25 to 30 gal. of crude tar, light and oil-like in character, as the main condensation product, from which will be derived (a) 5 gal. of motor fuel; (b) 2½ to 3½ gal. creosote oil; (c) 1½ to 2½ gal. lubricating oils, and (d) 8 to 12 lbs. lubricating grease." There will be also from this latter distillation a residual oil of tar-like character, suitable for use as fuel oil. Regular high-temperature practice gives about 12,000 cu. ft. of gas, but the heat valve is less (500 to 600 B.t.u.) The regular coke-oven also gives a higher yield of ammonia, as a part of the nitrogen in the coal remains in the low-temperature coke. The latter gives, however, from 10 to 20 gal. more of tar than the regular coke-oven, and this tar contains a larger proportion of the lighter and more valuable oils.

It is expected that the 400-ton plant at Walkerville will be in operation about October 1st next. Meantime the construction of the first unit of a 4,000-ton plant at River Rouge, Detroit has been undertaken by the Ford Motor Co.

A branch of the Royal Mint for South Africa has been completed recently in Pretoria.

Investigations by the Mines Branch of the Department of Mines, 1923

By JOHN McLEISH, Director

During the season of 1923 the Mines Branch will undertake field investigations of Mineral Resources and their technology and of the Mining Industry through ten parties, in addition to field studies directly related to laboratory investigations; and in the laboratories and experiment stations at Ottawa it will conduct a variety of tests, experimental and research work, on determining the character and values of ores, fuels and mineral products for their treatment and for the efficient recovery of their valuable constituents.

Field Investigation of Mineral Resources

The field investigations of Mineral Resources and of their technology are designed through published reports on individual mineral products to furnish the interested consumer, investor or prospector with a record of the localities where the occurrence of economic mineral resources has already been determined and with the available data as to the extent both of their occurrence and of their exploitation. To the discoverer, owner or expectant operator are furnished the collected and accumulated data respecting the physical and chemical characteristics of mineral products; descriptions of methods of mining and treatment commonly employed; the specifications as to the composition and character of the products required to meet market conditions; the uses to which the products are put; the industries in which they are employed, and the essential commercial data respecting markets, prices, consumption, etc.

L. H. Cole, with **H. A. Leverin** and **M. F. Goudge** in charge of sub-parties, will continue investigations, in progress during the past two years, of the alkali lakes of western Canada, with a view to determining their distribution and character and estimating the quantities of sodium and magnesium salts available. A study will also be made of the methods of preparing the salts for market and of market requirements.

Sodium sulphate, sodium carbonate and magnesium sulphate found in these deposits are important in industry and are at present largely imported for Canadian consumption. Sodium sulphate is the salt that occurs in largest quantity in these alkali lakes. At the present time the Canadian Kraft paper industry imports into eastern Canada from the United States about 35,000 tons per annum of this product and important quantities are also used by glass manufacturers. It is probable that the near future will witness developments of paper manufacture and other industries in western Canada that will utilize these sodium sulphate deposits with a minimum of transportation. These deposits are of limited extent but are such that their quantity can be ascertained within reasonable limits. A knowledge of our resources in this particular is essential to their intelligent administration, and is equal in importance to their utilization in domestic industry.

S. C. Ells will continue and complete his topographical surveys of the bituminous sands of northern Alberta from Fort McMurray to Township 100 on the Athabasca river. Serious study is being made by various companies and organizations of the possibilities of these sands as a source of bitumen for road making, as well as a possible source of oil.

V. L. Eardley-Wilmot will investigate natural abrasive materials in Canada. Studies will be made of the occurrence, character, methods of preparation for market, industrial uses, etc.

H. S. Spence will devote some time to further studies of the bentonite of Alberta and British Columbia, with particular reference to possible economic occurrences, uses and markets. Mr. Spence will also review present conditions and developments in several industries, on which special reports have already been issued.

A. W. G. Wilson will, if the work is not otherwise assigned, investigate the technology of the recovery of arsenic, the production of arsenious oxide and the uses and markets both in Canada and in the United States. This will supplement an investigation of Canadian occurrences of arsenic being made by the Geological Survey.

A. Buisson, A. H. Robinson and others will make general enquiries and collect information respecting progress being made in the development of the Mineral Industry, covering as many metals and products as available time and staff will permit.

R. T. Elworthy of the Chemical Division will make a field study and chemical investigations of natural gas in western Canada, with particular regard to the determination of the composition, character and gasoline content of these gases. Gases containing ethane and hydrocarbons other than marsh gas appear to be in considerable demand at the present time for the manufacture of carbon black. Exploration for petroleum in Alberta and other parts of western Canada is developing numerous sources of natural gas, many of which will for years be too far removed from centres of population to be available for ordinary industrial use, but which may prove to be valuable sources of a number of important by-products.

C. S. Parsons of the Ore Dressing and Metallurgy Division, will visit gold milling and metallurgical works in connection with laboratory investigations on gold ores.

J. H. H. Nichols of the Fuel Testing Division, will collect representative samples of coal from the mines of New Brunswick and Nova Scotia for laboratory and commercial scale tests, with particular reference to their coking qualities.

E. S. Malloch will make field studies of the present methods of utilizing and burning fuels both for industrial and for domestic heating.

Howells Frechette, Chief of the Ceramic and Road Materials Division, together with a ceramic engineer to be appointed, will make a general investigation of the brick industry in Ontario and Quebec and will conduct a special study of drying problems in this industry.

H. Gauthier will make a special study of the endurance of recently built highways in Ontario and Quebec, to determine the relative merit of the various types of material used in their construction.

R. H. Picher will continue the investigation of road materials adjacent to highways about to be improved in the provinces of Nova Scotia and New Brunswick.

Laboratory Testing And Research

The laboratories, or experiment stations of the Mines Branch are equipped for both small and large scale experimental work on ore concentrates; for comprehensive physical and chemical tests on fuels and oils; for complete physical and kiln tests on clays, ceramic and refractory materials; for complete physical tests on rocks, sand and gravel used for road building purposes; and generally for physical tests on structural materials.

Ore Dressing And Metallurgical Division

In this Division, under the direction of Mr. Timm, Messrs. C. S. Parsons and R. K. Carnochan, with the assistance of a staff of chemists are carrying on the following investigations on ore treatment.

Copper Ores: Experimental work on the concentration of (a) the lower grade copper ores of Hidden Creek, Anyox, B.C. Tonnage checks will be made to determine whether the results from the small scale laboratory work can be obtained on a larger scale; (b) the Flin-Flon disseminated ore of northwestern Manitoba; (c) the copper-gold pyrrhotite ores of Rossland, B.C., to improve efficiency of recovery of values; (d) copper-gold ore from the Belmont-Surf Inlet mines, Surf Inlet, B.C.; and (e) the copper ore from the mines at Copper Mountain, Princeton, B.C.

Copper-Nickel Ores: (a) Small scale tests on the concentration of the lower grade copper-nickel ores of the Sudbury district will be supplemented by large scale tests. (b) Further investigations on the determination of the precious metal values in the Sudbury ores, the Shebandowan copper-nickel pyrrhotite ores and other Canadian pyrrhotite ores, and in the concentration and reduction of products from these ores. This also is to confirm, on a larger scale, previous small scale tests.

Lead-Zinc-Silver Ores: (a) On the concentration of East Kootenay ores to determine the possibilities of improvement in cencentration and the most suitable reagents to use in flotation. (b) An investigation of the carbonate ores to determine a process for treatment.

Gold Ores: (a) On the treatment of Kirkland Lake gold ores; investigation of difficulties in making high recovery, (b) A test on the concentration and treatment of samples from the new gold fields in Rouyn Township, Quebec; (c) On the metallurgical treatment of typical Nova Scotia gold ores. It is believed that previous metallurgical practice did not result in a good recovery.

Iron Ores: An investigation has been begun on the leaching and electrolytic deposition of pyrrhotite ores and the roasting, leaching and electrolytic deposition of pyrite ores for the production of electrolytic iron and the recovery of the precious and non-ferrous metals that may be contained.

Molybdenite Ores: Tonnage tests will be made upon a shipment to be made from deposits near Amos, Quebec.

Flotation Re-Agents: Considerable progress has been made in an investigation begun last year into the use of various flotation re-agents in the concentration of mineral ores. The purpose is to stimulate the use of Canadian-made flotation reagents.

Pyrites: Tonnage tests are being made on the concentration and separation of pyrites ores from the Eustis mine, Quebec.

Asbestos: Some preliminary work has already been done, and it is proposed to continue an investigation of the wet separation of asbestos fibre from the rock.

Fluorite, Calcite and Barite: Small scale laboratory work on the separation of fluorite, calcite and barite in the fluorspar from the Madoc district has developed a promising process for the separation of these minerals, and it is proposed to conduct larger scale test work, to obtain further data and determine whether the process can be applied in practice.

Division of Fuels and Fuel Testing

Under the direction of Mr. B. F. Haanel, investigations are being carried on by E. S. Malloch, Technical Engineer; R. E. Gilmore, Chief Engineering Chemist and a staff of Engineering Chemists.

Lignite Coals: A continuation of work that has been in progress for a number of years including: (a) small scale work to determine the feasibility of carbonizing the lower grades of Alberta coals; (b) determination of the feasibility of briquetting the carbonized residue, obtained at different temperatures, from lignite coals.

Bituminous and Other Coals: (a) Relation of the coking properties of certain Alberta coals to their sparking qualities when burned in railway locomotives; (b) general classification of Canadian coals according to the area in which they are found and according to their general characteristics and chemical compositions; (c) investigation of the physical properties of different Canadian fuels and their products.

A special investigation will be made of New Brunswick and Nova Scotia coals with particular reference to their possible use in the production of a domestic, or house heating coke. This will include detailed chemical examination of the coals followed by large scale coking tests on selected coals and on mixtures of coals.

Peat: (a) Relation of degree of maceration to the drying and handling properties; (b) effective heat pressure and reagent treatments on the structure and chemical composition of peat.

Oil Shales: Development of standard methods of examination; (b) adaptability of oil shale for refining purposes and also as a motor fuel for internal combustion motor engines.

Crude Petroleum and Oil Products: (a) Canadian shale oil as a source of gasolene, illuminating, lubricating and fuel oils, etc.; (b) general examination of crude oils and crude asphaltic bitumen occurring in Canada.

Gasolene and Lubricating Oils: Survey of gasolene and lubricating oils sold throughout Canada, for the purpose of deciding on the feasibility of establishing standard specifications for each, for use (1) by various government departments and (2) by the general public.

Other Motor Fuels: Adaptability of natural and synthetic motor fuels such as industrial alcohol, bensole ,synthetic alcohol from a producer or natural gas for use in variable compression internal combustion engines.

Pulverized Fuel: The testing of pulverized peat, lignite and other coals on a commercial scale to determine value for the generation of steam.

Domestic Heaters: Investigations are being continued having in view the determination of efficiencies of fuels and other factors and the suggestion of alternatives in design of heaters to permit the more efficient utilization of fuels other than anthracite.

Gas-making Coals: It is proposed to investigate the feasibility of utilizing Nova Scotia high sulphur coals for gas making.

Division of Ceramics And Road Materials

Ceramics: Laboratory tests on clays, shales and other raw materials of the ceramic industries and on brick and other clay products will be conducted within the limitations fixed by available staff; studies will be made to determine the cause of faults in brick and tile of Canadian manufacture and to devise methods for overcoming them, and investigation will be made of the drying properties of clays; experiments will be made on pottery bodies and glazes and on Canadian magnesite for refractory purposes.

Road Materials: The testing of samples of rock, gravel and sand, to determine their suitability for highway construction, is carried on chiefly during the winter months by the engineers who during the field season are engaged in the study of field conditions and in the collection of the samples.

Investigation is being made of the technique of the testing of road materials determining the accuracy of the various tests in use and their correlation to the life of the materials in service with the object of improving methods of testing.

RAND PRODUCTION IN MAY

The output of the Transvaal gold mines for May has been officially declared at 786,584 fine ounces, an increase of 42,933 ounces over April. As compared with May, 1922, production was greater by 156,778 ounces. Numerous individual increases are noted in the returns from the various mines, notably in the Rand mine group. Not only have larger tonnages been crushed, but mining costs have been lower. The reports of the annual meetings of the gold companies held at Johannesburg all sound the keynote of improved mining conditions on the Rand, of greater efficiency and economies, restored control, and of the prospect of effecting still further savings. Valued at 86s. an ounce, an increase of 1s. over the previous month, May's output amounted to £3,382,225, an increase of £221,708 over April and an increase of £485,210 over May, 1922.

Natives employed in the gold mines at the end of May numbered 175,591, as against 178,337 in April. The number of Europeans employed in the mines is about 18,000. On increased supply of natives for the mines is anticipated from Transkei. It has been reported, though not officially confirmed, that the conciliation board has given a majority decision adverse to the mechanics' demand for the 30 per cent. increase in wages. — Commerce Reports.

MICA DEPOSITS OF THE UNITED STATES

In a monograph of 342 pages (Bulletin 740, United States Geological Survey) D. B. Sterrett gives a complete account of the mica deposits of the United States, nearly all of which are muscovite deposits in pegmatite dikes. A little biotite has been mined. The valuable phlogopite deposits of Ontario and Quebec seem to have no parallel in the United States. But muscovite has been mined in 26 states, ranging from Maine to South Carolina, and from New York to California. While it is often whiter than phlogopite and therefore better suited for such uses as for lanterns, stoves, lamp chimneys, and lantern slide covers, its greater hardness and brittleness make it inferior to phlogopite for the manufacture of electrical motors and dynamos. The supply of phlogopite has come principally from Canada, a small amount being imported from Ceylon. In 1921 the total production of rough trimmed and cut mica in the United States was 741, 841 pounds, valued at $118,513. To this must be added 2,577 tons of scrap mica valued at $56,849, making a total value of $175,362. The total value of mica imported in the same year was $1,091,906.

The uses of mica are extending. "Ground mica is used in largely increasing quantities for the decoration of wall papers, for the manufacture of lubricants, fancy paints, rubber goods, molded mica, and roofing papers. Bran mica and coarser grades mixed with other materials furnish fireproof and heat-retaining coverings for steam pipes and boilers. In experiments made by the Grand Trunk Railway on five locomotives protected by different materials, mica covering saved about 92 per cent of the heat radiated from a bare boiler and was about twice as efficient as sectional magnesia block covering." *Tung ash* is a bronze colored material made by calcining a hydrated biotite. It has been put on the market of late years for decorative purposes.

STUDY OF MILLING PROBLEMS

Prof. E. A. Hersam, Massachusetts Institute of Technology, representing the United States Bureau of Mines, in a general study of milling problems being made in co-operation with the American Institute of Mining and Metallurgical Engineers, has made an extended tour through Ontario and Michigan for the purpose of conferring with the operators of mills and examining the work of these mills. An object of these visits has been to bring into comparison the problems which are being met in the separate mining regions where milling is practised, and to determine which problems are of common concern. A report is being prepared in which the aim will be to make what may be stated of the nature of the research in the milling industry that is being carried on, as practised upon ores, and to indicate, so far as the knowledge may be obtained or desired, the need for fundamental research, in order to solve the problems that are now presenting themselves in connection with the milling of ores, and which if solved would result in increased efficiency and the advancement of the industry.

MOTOR FUEL FROM PRICKLY PEAR

A company has been formed in South Africa to make industrial alcohol and allied products such as vinegar from the prickly pear, a cactus which is a menace to agriculture and is available in very large quantities. It is said the alcohol, to be used as a basis for motor fuel, can be made profitably to sell at 2 shillings per gallon. At present all motor spirit is imported and costs about 3s. 7d. per gallon.

The production of arsenic in Canada in 1922 amounted to 2,576 tons, valued at $321,037, which was an increase of 73 per cent. in quantity, but only 37 per cent. in value over the shipments for 1921. Approximately four-fifths of this was produced in the smelting of the silver-cobalt-nickel ores of Northern Ontario.

EMPIRE OPPORTUNITIES

Review of Certain of the Empire's Mineral Resources.

(Extracted from the "Raw Materials Review")

"Trade within the Empire" has for many years been political policy; but during and since the war it has ecome an economic necessity.

In the past, however, its extension has been hamered very considerably by lack of recognition on the art of the British manufacturers and merchants, alike f the resources of our colonies and the opportunities f increased trade which their development and conequent prosperity offers.

This survey, whilst in the main general, has aimed t being particular in instances which appear to offer eculiar opportunities for manufacturers in this country, and it has been compiled in the hope that it may e of some specific service to those who are inclined o profit by the chances which our Empire can offer of eliable and progressive supply sources.

Newfoundland's Minerals

Newfoundland, thanks, on the one hand, to the eablishment of an active High Commissioner's office in ondon, and, on the other, to the appreciation of the ossibilities of the water-power available throughout he island, may well become—given reasonable applicaion of intelligent enterprise and capital—a really imortant centre of mineral production.

The iron ore mines are the second largest in the vorld. In the early eighties Newfoundland was the ixth copper producer of the world, when three mines, mploying collectively 5,000 men, were in operation. These mines closed down in 1894 owing to the low rice of the metal (6½ c.) due to the collapse of the opper pool of that day.

On the following copper properties sufficient work as been done to warrant the hope that they may beome producers: — Goose Cove, St. Julien's, Baie Verte, Tilt Cove, Burton's Pond, Bett's Cove, Rogue's Harbour, Stocking Harbour, Naked Man, Colchester, Walsh's Cove, Shoal Arm, Little Bay Head, Little Bay, Whale's Back, Davies Pond, Lady Pond, Hall's Bay Head, Bob's Head, Island Rock Cove, near Springdale, Gull Pond, Rabbits' Arm, Sunday Cove Island, Placentia Bay, York Harbour, Chimney Cove, Gregory Cove. All these deposits, with one exception, are at tide water. Many of them have proven tonnages which would warrant operations of over one thousand tons daily; several over three thousand. The average copper content of the ore is said to be about 60 lbs. per ton. The average copper content of the ore mined on the American Continent is about 40 lbs.

Were sufficient capital applied to the well-known ore deposits it is estimated it might be possible to produce in that country a daily average equal to that now produced in the whole American Continent.

Besides iron, coal, copper, galena, manganese, molybdenite, nickel, silver, antimony, limestone, marble, gypsum, barytes, salt, petroleum, slate, clays, and infusional earth exist in commercial quantities only awaiting development.

Development in Tasmania

Tasmania has also set itself seriously to work to develop its extensive water-power resources. The hydro-electric scheme, the last section of which was opened by the Governor-General, Lord Forster, in January, develops 60,000 horse-power. A large portion of this power has been leased to the Electrolytic Zinc Co. of Australia on very moderate terms. This company has installed electrolytic works at Risdon with a capacity of producing 45,000 tons of electrolytic zinc per annum, and it is stated that the works are now working at full capacity. Another large industry supplied with electric power from this scheme is the calcium carbide plant at Electrona, while other smaller consumers of power in Hobart are being supplied from the same source.

The cost of the scheme has been great, but it is satisfactory to learn that the portion which has been in full commission has earned more than sufficient to pay the interest on the cost of its installation. It should be emphasised, however, that it is no part of the Tasmanian Government's intention to look for a large revenue from this enterprise. The primary purpose is to create new industries by the supply of electric power at the lowest possible rate. This is another proof of the sagacity of the Tasmanian authorities. Development of new industries is likely to prove a far more prolific and permanent source of revenue than could be expected from attempts to make the hydro-electric enterprise a large profit-earning one.

Projected Tasmanian Enterprises

The success which has attended this initial enterprise has given rise to the contemplation of further schemes of a like character. The water-power resources of the State have been officially surveyed and computed, and suitable sites for the power works selected. There is about 20,000 horse-power available on the Huon River at no great distance from Hobart; in the central part of the island there is 50,000 horse-power available on the River Ouse, 13,000 on the Upper Shannon River, and 30,000 on the Upper Derwent River. On the West Coast, 65,000 horse-power can be obtained from the King River, and a further 25,000 horse-power in the Lake Rolleston district. These will be developed as fast as industry seems likely to absorb the power, but it is understood that one of these sources for supplying power to Launceston will be put in hand forthwith.

From a metallurgical point of view Tasmania is also relatively well endowed. Mount Lyell copper and Mount Bischoff tin have for long occupied prominent positions in the metallurgical world. In fact, for a small State, the mineral production has been remarkable. According to the annual report of the Department of Mines for 1921, the value of the minerals won up to the end of that year amounted to £46,910,723, the principal contributing metals being — gold £7,510,481; copper, £16,118,494; tin £14,131,491; and silver-lead ore, £6,886,113. The mining of the lead-zinc deposits, which, owing to the refractory nature of the ores, has been neglected, is now likely to become an important part of the mineral industry. The treatment of these difficult ores is no longer outside the scope of modern metallurgical methods. Interesting, also, is the relative abundance of the rare metals osmium and iridium in the island. These occur and

are mined together; in 1919 the production amounted to 2,009 ozs., valued at £77,114, or about £38 per oz.

Tasmanian Coal

Coal for metallurgical purposes is sufficient, even though not present in overwhelming abundance. It is true that Tasmania can scarcely aspire to be a great steel and iron-producing State, because supplies of both coal and iron ore are moderate. There is, nevertheless, the possibility of a considerable industry of this character, particularly if cheap power is available to permit of the electric smelting of the iron ores.

Petroleum in commercial quantity has not yet been found on the island, but there is good authority for thinking it will be discovered. At any rate, there is no doubt of the abundance and richness of Tasmanian oil shale, which is already being exploited on a moderate scale.

The future of Tasmania is exceedingly promising, and it is gratifying to note in this small section of the Empire on the opposite side of the world such excellent signs of progress.

Rhodesia is another region that deserves watching and encouragement, and will repay all the attention given to it. If we permit ourselves a little of that geographical licence so natural to dwellers in so small an island, the centre of so vast an Empire, we may say that Rhodesia is next door, or fairly close to, Kenya, Tanganyika, Nyassaland, Bechuanaland, and even Basutoland. And even the briefest survey of the resources and potentialities of that widespread region opens an undreamed of vista to the imagination. Let Rhodesia suffice for the moment. We quote from the report of the Acting Secretary of Mines, to whose "chief" we may be allowed to offer our congratulations on the honour conferred on him.

Rhodesian Gold Production

The total production of gold in 1922 amounted to 652,791 ozs., valued at £3,111,468, which shows an increase over 1921 figures of 67,266 ozs., but a decrease in value of £105,807. This decrease was attributable to the fall in the premium. The amounts paid in respect of premiums on gold and silver amounted to £320,022, as against £698,395 for the previous year, representing 10.20 per cent. of the total value of the gold and silver, as compared with 21.59 per cent. for 1921. The banks continued to pay 77s. per standard ounce in the first instance, and the premium payments were adjusted later when the gold was sold in London. There were four payments of premiums made—viz., August to October, 1921, 16s. 6d; November, 1921, to January 1922, 10s.; February to April, 1922, 7s.; and May to July, 1922, 7s. per standard ounce. Taking the total gold value (including premiums) the amount of the output works out at £4.766 per fine ounce, or £4 7s. 5d. per standard ounce.

The number of gold producers was 413, which is approximately an increase of 30 per cent. over the year.

The dividends paid by the larger gold mining companies during 1922 amounted to £611,639, chief amongst these being the Globe and Phoenix Gold Mining Co., Ltd., which declared a dividend of 54.237 per cent.; Rezende, Ltd., 40 per cent.; Lonely Gold Mining Co., Ltd., 30 per cent.; and the Shamva Mines, Ltd., 27½ per cent. Rhodesia development and miscellaneous companies paid dividends during the year amounting to £256,801.

Asbestos, Chrome, Coal and Mica

The total production of asbestos for 1922 and up to date is somewhere in the region of 17,000 tons, of long fibre and good quality. For some purposes it is considered — so we are informed by a "client" of the Raw Materials Review, who, we trust, will reap some benefit from the introduction we were able to give him to Rhodesian asbestos — more suitable than the Canadian product. In any case, Canada and Rhodesia can show, for all purposes, a firm front to competition from Central Europe, so far as asbestos is concerned.

Chrome again shows a promising increase of 43,000 tons over 1921, the output being declared at 93,475 tons with a value of £302,880.

Coal also promises well for the future. The Wankie colliery is responsible for the total output for 1922—516,000 tons of good steam coal. Experts estimate the resources of the coalfield at six thousand million tons. For copper the output was 3,388 tons, value £201,022—300 tons more than in 1921. The value of copper for the year, including adjustments, amounted to £59 per ton, as compared with £65 for 1921.

In the mica output a decrease of 19 tons has to be recorded over the 1921 figures, the output being 66 tons, valued at £61,561, in 1922, as against 85 tons, valued at £20,747, for 1921. The value averaged £250 18s. 5d. per ton, which figure is, however, subject to adjustment when account sales are received. Owing to the difficulty which has been experienced by the producers in selling the mica in England, it has not yet been possible to arrive at the actual value received for the amount exported. There has been a slight revival on the fields, and increased attention is being paid to grading, and machinery has been introduced for the manufacture of punch mica. One of the mines producing a clear ruby mica has been opened up to a depth of 130 ft. and developed for a length of 500 ft. along the strike.

Tin, Arsenic and Tungsten

Only half a ton of stream tin was won from the Ranga claims in the Victoria district, valued at £61. It is hoped that the recent rise in the price of tin may be the means of producing more activity in the prospecting for tin in the country and the development of the claims already held.

Arsenic was produced in the Bulawayo and Umtali districts from two mines. The output was 497 tons, valued at £11,774, as against 361 tons and £11,263.

An amount of 45 tons (fine contents) of scheelite was declared at the end of the year from the Golden Valley Mine, in the Gatooma district, valued at £1,600. This shows a considerable increase over last year's figures. Excellent accounts are received as to the high quality of this product. Another by-product obtained from the Golden Valley Mine is red oxide, which is having a ready sale for painting purposes. It will be interesting to see how this oxide compares with the Indian red oxides, which are greatly favoured by expert users.

Minerals, however, form only a part of the resources of what we may perhaps call British East and South-East Africa. Cotton, timber, fibres, nuts, coffee, hides exist in profusion — to say nothing of cattle, dairy produce, fruits (citrus for one)—in this vast region, which surely deserves attention among those who represent Empire enterprise in this country.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NOVA SCOTIA

Springhill Works and Drumheller Strikes. — For many years, Springhill miners were notorious in the Maritime Provinces; their record of striking for trivial causes was known everywhere. However, the time came when it was proved to their entire satisfaction that strikes avoided were better than strikes carried through to a finish. Therefore today, when the men of other collieries of Nova Scotia are out on strike on a mere pretext, but in reality through the manipulation of the communists, Springhill is at work, and intends to remain at work until called out by President Lewis of the International. There is no just cause for strike among the miners of Nova Scotia and when one reads that Alberta miners are on strike in sympathy there is a humorous side to the matter. The miners of the province are on strike against the use of the Provincial Police while the Drumheller men are on strike against the use of the regular forces of Canada. Cape Breton miners rather like the soldiers for in the past they found them very good fellows and are not, therefore, clamoring for their removal. They are opposed to the Provincial Police because they will not fraternize and are a very effective body.

A Communist Official Report on Sydney Labour. — The struggle in Nova Scotia is only part of the campaign now being waged by the Communists of Canada, United States and European countries. Only a short time ago a survey was made of labor by one of the Communists, whose report is most interesting and illuminating. Speaking of the miners of Cape Breton, he says "they are one hundred percent behind the Red Executive, while fifty percent of those on the Mainland also support the Reds". He admits "there are no signs of growth of the Workers Party of Canada, and that the miners while supporting a Red Executive are far behind in the political sense. This view has been held by all Communists who have visited Nova Scotia." He goes on to say that the principal efforts of the Communist leaders in the immediate future will be devoted to the organization of the Sydney steel workers, where the spirit of the union members is said to be excellent from a Communist viewpoint. He further states that he had never seen such a militant spirit amongst any miners since the days of the old Western Federation of Miners. He is confident that the "Red" leaders are in the saddle for some time, and that no wire pulling by Lewis can affect them; also that "the *Maritime Labor Herald* is improving and is regarded as a powerful weapon in the hands of capable Communists." Thus, from their own reports, none need be deceived as to the underlying cause of all the labor agitation during recent years. While there is, no doubt, some cause for the steel workers to feel aggrieved, yet it is commonly agreed that the steel workers' local, in acting against the advice of the international officers, was under the control of the Communist party. These same officers leading the local have continued to misrepresent the true conditions at the steel plant, where many union men are now at work and intend to remain so.

When Truth is Known, Communist Rule will Cease. —There is much misrepresentation of the true situation among the industrial workers of Cape Breton, due to two causes. The first is the propaganda of the Communists, who have convinced the labor organizations of Canada that the Sydney workers are maltreated and oppressed — an utter falsehood. The fact is that hundreds of Nova Scotia miners today are asking one another, "What are we striking for?" The Communist element, who forced the strike, claim to be in the ascendency today. It is unthinkable that these firebrands will remain permanently between the workmen of Cape Breton and their employers. Once let the workmen understand that they are being led by the noses into paths they know not of and the rule of the "Reds" will last no longer. The second cause is the bungling management of former strike settlements. Outsiders have interfered too much with the internal labor affairs of Nova Scotia with the result that the agitators scored a victory in each case.

The arrest of McLachlan and Livingston for a short time intensified the feeling of the miners; but that is beginning to wear off. There are thousands of moderate men who detest the action of their radical executive. There is now added dissatisfaction since in response to President J. L. Lewis' telegram, ordering the strike to be called off, Vice-President McIntyre of Local No. 26 has explained to his followers that the strike is political and not industrial. The cat is out of the bag; it is a strike for Communist rule. This justifies fully the presence of the provincial police and the military forces. It should be remembered, also, that these forces were called in, not on account of the strike, but on account of the violence of the strikers.

Reorganization of District 26 is Imminent. — The recent strike vote shows that the miners are decidedly against the strike. Out of a total of 13,000 organized mine workers in Nova Scotia only 5,500 voted on the strike ballot and of these only 3,200 voted for a strike, 2,300 being against. But the men are actually on strike, and the moderates have no leader strong enough to represent their opinion. The International headquarters recognizes this fact and is tired of the disturbed condition of the District. It is in a better position than any other trades organization in Canada to know the facts for these have been submitted to them by a Commission sent into Nova Scotia to ascertain and report on the cause of the continuous agitation. There is no doubt in the minds of those in close touch with labor affairs that a re-organization of the District must take place. That this will come when the time is ripe, is beyond doubt, for those who have followed the work of President Lewis in the United States during the last year know that he will only move when he is sure of success. This re-organization cannot come too soon. It will bring with it peace to a community goaded to the point of armed resistance by men beguiled and misled by brainless leaders.

Final statistics of copper production in the United States in 1922 show a smelter output of 950,285,947 lbs., and an average price per pound of 13.5 cents.

BRITISH COLUMBIA

Florence Mine Operations — F. R. Wolfe, president of the Florence Mining Co., states that the Florence Mine is producing at the rate of 225 tons a day and that some 150 tons of ore and concentrate are being shipped every tenth day. Two locomotives operate between the mine and the mill and 85 men are employed on the property.

Copper Bounty Stimulates Industry — L. W. Humphrey, member of the Canadian House of Commons for the District of West Kootenay, referring to the Dominion Government's action in placing a bounty of one and one-half cents a pound on Canadian copper rods and bars, said that the result would be the opening up of a British Columbia copper rod mill built at a cost of close to half a million dollars. Mr. Humphrey was speaking of the plant of the Consolidated Mining & Smelting Co. at Trail. He also said that employment would be created for from three to five hundred men and copper would be produced in Canada for which at present $3,500,000 is spent annually in the United States. Within thirty days of the coming into effect of the bounty the mill should be in operation.

Eastern Party Inspects Portland Canal Properties — Samuel L. Silverman, of New York, heads a party that left recently for the Portland Canal District. Among those with him are Malcolm Stobie, of Stobie & Furlong, Toronto, Ont.; R. B. Lamb, mining engineer of New York, advising Mr. Stobie; Major W. D. Wilson, of Hamilton, Ont.; and Judge F. H. Phippen of Toronto, Ont. Mr. Silverman is interested in the development of the "Forty-Nine" and "Bush" properties, situated in the same section as the Premier Mine, and he and his confrères intend inspecting personally these and other mining prospects.

Promising Find in Clinton District — The Whitewater Gold Fields Co. is developing the Windfall Group in the Whitewater section of the Clinton Mining Division. A gang of twelve men is drifting on what is said to be rich ore and a Ross mill is being installed. The district is being well prospected and a weekly pack train with 20 horses is providing a transportation service from Bridge River into this new and promising mining country.

Noble Five Bonded — The Noble Five Mine, Lardeau District, has been bonded by Vancouver interests and further development is planned.

Porland Canal News — The Murdock Group of eight claims on the east side of Bear River, Portland Canal District, is being prospected bythe Northern Construction Co. There are some good showings of high-grade silver-lead ore on the property. Prospectors are being advised to give some attention to this locality, which now can be reached with comparative ease over a trail newly constructed by the Government up the south bank of Surprise Creek.

The Bear River zone has come more into favor with the statement that the showings on the Dunwell Mine are improving. It is said that in the lower tunnel of the Dunwell, which has been driven 290 feet and reaches a vertical depth of 240 feet, the vein has been penetrated for 40 feet without reaching the footwall and that a large proportion of the ore is of good milling grade, while some gives high returns in silver.

Major R. F. Crichton, of Vancouver, has reached Alice Arm with a small crew of men to resume the development of the Homestake Group of claims located 26 miles up the Kitsault River. About 170 feet of tunnel work has been done, the vein having been cut at 123 feet. No. 2 Tunnel is to be exteended and other work proceeded with having in view the blocking out and proving of a considerable body of ore.

Prospective New Producer in West Kootenay — The "Iva Fern", situated on the west slope of Cultus Creek, West Kootenay, and within comparatively easy reach of Kootenay Lake, is reported to have been developed by the Standard Silver-Lead Co. with exceptionally good results. The latter company has an option and bond on the property for $100,000 which it took up after the Consolidated Mining & Smelting Co. of Canada allowed their interest to lapse. The Standard Silver-Lead continued the underground work started by the Consolidated and is reported to have opened up a large body of silver-lead-copper ore, in which there is some high-grade, while the remainder is of good milling grade. The tonnage in sight is said to be increasing daily and the Company is believed to have established another important Kootenay producer. The construction of a wharf by the Dominion Government on the lake side is being sought. Further road work is asked and plans are being discussed for the installation of a concentrator and a compressor plant.

Trail Ore Receipts — Ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co., from June 22nd to 30th inclusive, totalled 13,241 tons. The shippers, including some of the notable contributions of the first days of July, follow: Hercules, Burke, Idaho, 133 tons; Alamo, Alamo, 43; Bell, Beaverdell, 35; Company Mines, 11,828; Emerald, Salmo, 39; Knob Hill, Republic Wn., 104; Lone Pine, Republic Wn., 385; Quilp, Republic Wn., 419; Rosebury-Surprise, New Denver, 52; Silversmith, Sandon, 165; and Victor, Three Forks, 32.

The Late R. G. Edwards Leckie and Windpass — General R. G. Edwards Leckie, a mining engineer of prominence in Western Canada who had an exceptional overseas record in connection with the Canadian forces in the Great War, died recently in Vancouver, his home city. His sudden death is mourned by the community to which he belonged and is keenly regretted throughout the Province. This applies particularly to mining men, as all engaged in that business in British Columbia were acquainted with General Leckie. Latterly he had been engaged in putting the Windpass Mine at Chu Chua upon a producing basis. Through his efforts Messrs. Trites, Wood and Wilson, of Fernie, who made fortunes through their interests in the Premier Mine, have been assisting in the financing of the Windpass. Mining machinery has been installed and camp buildings erected. It is stated that the Windpass now is an assured mine and it is believed that its success will lead to the opening of other properties in the district.

HYDROGEN SULPHIDE AN ACTIVE POISON

That hydrogen sulphide, a gas often present in mines and tunnels and in various industrial plants, is an extremely poisonous gas, although not heretofore fully recognized as such, is disclosed by an investigation just completed at the Pittsburgh experiment station of the United States Bureau of Mines, and described in Serial 2491. The investigation establishes the fact that acute poisoning of men can be produced by low concentrations of this gas and may result in respiratory paralysis followed by heart failure and death.

Hydrogen sulphide is sometimes present in mines, railroad tunnels, sewers, and marshes; and is found in various stages of the manufacture of sulphuric acid

nd in the distillation of petroleum, particularly those ils known as high-sulphur crudes; also about some as wells, gas plants, and smelters.

FALL MEETING OF ELECTROCHEMICAL SOCIETY

The next meeting of the American Electrochemical Society is to be held in Dayton, Ohio, on September 27th to 29th. The papers will include a symposium on "Recent Progress in Electrolytic Refining," under the chairmanship of F. R. Pyne, of the United States Metals Refining Co. There will be an innovation, consisting of round table discussions of electric furnace brass foundry practice, organic electrochemistry, chlorine and electroplating. Visits will be made to local plants.

A legal minimum wage above that fixed by economic conditions signifies that the recipients are relieved to a certain extent from the struggle for existence that is the natural lot of all living beings. When this minimum wage does not exceed the literal "living wage", its existence would seem to be justified. If it is above what is required to support life decently, its justice is doubtful.

The Messina copper mine in Rhodesia is again in operation. It was closed down in 1921, due to the low price of copper. Its capacity is 300 tons of copper a month. The destiny of an important part of Rhodesia's prospective railway system is linked up with the success of this mine.

Advertisements other than "Employment Wanted" or "Employees Wanted" will be inserted in this department at the rate of 20 cents per agate line (14 agate lines make one inch). $2.80 per inch, each insertion, payable in advance. Space measured from rule to rule. When four or more consecutive insertions of the same advertisement are ordered a discount of 25 per cent. will be allowed.

Advertisements of "Wanted Employment" or "Wanted Employees" will be inserted at the rate of two cents a word, net. Cash must accompany order. If box number is used, enclose ten cents extra for postage in forwarding replies. Minimum charge 50 cents.

FOR SALE

Gold property in Nova Scotia. Wide mineralized belt, 6 dwt. Recent shipment to Nova Scotia Technical College from seven-foot vein ran $18.00 per ton. Will sell, or will give interest to party willing to develop property and erect mill. Inspection invited. Particulars on request.
— PERCY WHITE, Stellarton, Nova Scotia.

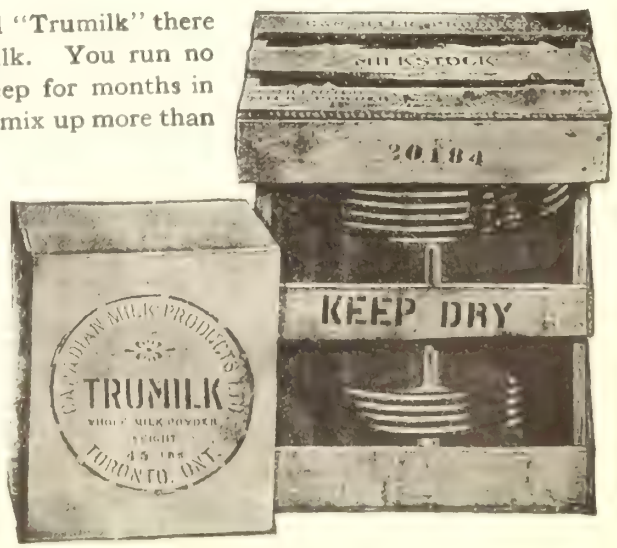
There's No Worry that Hot Weather Will Spoil the Milk Where "Milkstock" and "Trumilk" Are Used!

IF the camp cook has "Milkstock" and "Trumilk" there is never a worry caused by poor milk. You run no chance of milk spoilage. They will keep for months in the original containers—and you do not mix up more than is needed at the moment.



"Milkstock" (skimmed milk powdered) and "Trumilk" (whole milk powdered) should have a regular place in your camp stores. "Trumilk" is used wherever a full cream milk is needed. "Milkstock" will fill all requirements for milk for cooking purposes. You really should have a supply of both.

If you do not now use milk in this convenient form, try it. Samples will gladly be sent you free of charge.

MINES BRANCH

Recent Publications

Talc and Soapstone in Canada, by H. S. Spence.

Titanium, by A. H. A. Robinson.

Summary Report of Investigations made by the Mines Branch during the calendar year ending Dec. 31, 1921.

Phosphate in Canada, by H. S. Spence.

The Preparation, Transportation and Combustion of Powdered Coal, by John Blizard.

Road Materials along the St. Lawrence River, from Quebec Boundary to Cardinal, Ont., by R. H. Picher.

Barium and Strontium in Canada, by H. S. Spence.

The Coal-fields and Coal Industry of Eastern Canada, by F. W. Gray.

Analyses of Canadian Fuels. Part I to V, by E. Stanfield M. Sc., and J. H. H. Nicolls, M. Sc.

Graphite, by H. S. Spence.

Gas Producer Trials with Alberta Coals, by J. Blizard and E. S. Malloch.

The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the developing of the general mining industry of Canada:—

Fuel Testing Laboratory.—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.

Ore-Dressing Laboratory.—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.

Chemical Laboratory — Analyzing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.

Ceramic Laboratory.—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.

Structural Materials Laboratory.—Experimental work on sands, cements and limes is also undertaken.

Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to **The Director, Mines Branch, Department of Mines, Ottawa.**

Applicants for publications not listed above should mention the precise area concerning which information is desired.

Summary Report. The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist's report is required, or what subject they are interested in.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

Communications should be addressed to **The Director, Geological Survey, Ottawa.**

Ontario's Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

Hon. H. MILLS, Minister of Mines

Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth $48,128,387,of which the metallic production was $27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

Year.	Value.	Year.	Value.
1891	$4,705,672	1906	$22,388,383
1896	5,235,003	1911	41,976,797
1901	11,831,086	1916	65,303,822

Dividends.

Dividends and bonuses paid to the end of 1921 amounted to $23,140,734 for gold mining companies, and $84,388,185 for silver mining companies or a total of $107,528,919.

Mining Regulations.

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 par acre, depending on location in unsurveyed or surveyed territory.

Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Publications.

For list of publications, illustrated reports, geological maps and mining laws, apply to

CANADA WIRE & IRON GOODS COMPANY
HAMILTON

The contributing factors in making good Wire Rope are:

Men who know how
The best grade of materials
The most Modern Machinery

We have all 3 and are producing the goods. Give us a trial.

Our Wire Rope Catalogue is an invaluable reference book and contains many helpful ideas on the care of wire ropes and cables as well as information on the best kind of rope to use on all classes of work. A copy sent upon request.

Our other lines of Manufacture are Wire Cloth for all uses, Perforated Metals, Wire Pulp Mats, Clothes Lockers, Machinery and Window Guards, Pulp Mats, inquiries solicited.

Let Hercules Oil Increase Your Profits

Steam-distilled pine oil is conceded to be the best flotation frother known. Moreover, it is the cheapest flotation reagent in the long run because it recovers the greatest amount of concentrate per ton of ore.

This fact has found favor for Hercules Pine Oil with many flotation operators and engineers.

Hercules Pine Oils are produced under strict chemical control. The grade of oil which best meets your needs having been determined, we can supply that grade in uniform shipments.

We invite correspondence and offer the services of our technical staff in helping you solve your flotation problems.

PIPE BENDS IN ANY SIZE OR SHAPE

Pipe bends in all sizes and practical shapes are supplied by Crane Limited. They can be provided in either full weight, extra strong or double extra strong wrought pipe fitted with screwed, shrunk, Cranelap or Craneweld flanges of cast-iron, ferrosteel, malleable iron, cast-steel or forged steel. Crane pipe bends are produced in a plant which is fully equipped for bending pipe to any shape, true to specified dimensions. Each unit is tested under hydraulic pressure before shipment.

DODGE

Service To Power Users

When you buy Power Transmission Units from us you get more than mere Equipment. You have placed at your command the resources of the largest works devoted exclusively to the manufacture of Power Transmission Machinery.

We make a Complete Standardized Line. All parts are interchangeable, and, should the occasion arise, you can rely upon getting delivery of any standard part at a moment's notice.

Foundry and Engineering Department

Mill Superintendents have told us time and time again that the advice of our Foundry and Engineering staff has been most helpful to them in laying out plant and in the design of power units for special purposes, particularly Conveyor Equipment.

The strength of Dodge Service to Power Users is, that it is practical; that it is experienced; that it is reliable; and that it has the will, intention and ability to give satisfaction.

Call upon us for extra special service — we will not fail you.

PROVINCE OF QUEBEC

MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

MINER'S CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms. on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONORABLE J. E. PERRAULT,

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

Assisting in the Development of the Mining Industry

It is essential that the peculiar banking needs of those engaged in the exploitation of Canada's natural resources be met with special facilities.

The Imperial Bank, ever a constructive element in the progress of Canada, long since realized the need for interested financial service to enable the proper development of the mining industry.

By opening branches throughout the mining districts and continually adding to them, as necessitated by expansion, this Bank has materially assisted in the development of the industry throughout Canada.

Those whose business is mining will find our facilities adequate and our knowledge of conditions valuable.

BETTER TIMES AHEAD FOR NOVA SCOTIA

The intervention of John L. Lewis, President of the United Mine Workers of America, in the Nova Scotia coal miners' strike has virtually settled it. Mr. Lewis' public denunciation of the tactics and aims of the insurgent labour leaders in Cape Breton is nothing if not direct and vigorous, and is reminiscent of his method of combatting the claims of employers when he has been in conflict with them. The "moderates" are in the saddle once more, and after their sad experience under Communist control, it seems probable that sounder policies and saner action will now become the order of the day.

Among the first of the striking locals to return to work was Caledonia, which made its decision last Thursday. It is significant that the first of the signatures appended to the resolution recommending similar action to the other locals is that of Robert Baxter, President of District 26, U. M. W. A., until the incidence of "Red" rule last year. It will be recollected that, on being turned out of office by the extremist vote, Robert Baxter returned to his former occupation as a miner, which he still pursues. The Baxter régime was not notable for any dearth of excitement in the way of strikes; but there was no hint of Communist rule in the action of his executive, the strikes being conducted with due regard to the accepted "rules of the game," with the sole object of bettering the daily lot of the mine workers.

Silby Barrett, formerly the representative of District 26 on the International Board in Indianapolis, is now the leader of the union in that district. At the time of writing it appears that he will be accepted by all the locals, even if not universally acceptable. He has shown himself a good friend of the miners, and an outspoken enemy of the extremists. He has the full confidence of the international executive of the miners' union, and is backed by the officials of the British Empire Steel Corporation. Altogether, he begins his term as leader with a record and under auspices that promise sound and effective administration.

The leaders of the extremist group have taught their followers to "bore from within:" It is this insidious policy that brought them into power in their union last year. The miners now have seen whither the prophets and the policies of Communism would lead them. We would judge that they have marked well the result, and that the "boring" tactics will have little effect from now on.

There is no doubt that the workers in the collieries and steel plants of Cape Breton have now, as heretofore, some just cause for complaint against their employers, the British Empire Steel Corporation. Since its inception, part at least of the management of the Corporation have shown a disposition to close the breach between their workmen and themselves, which, from small beginnings, has grown to alarming proportions during recent years. They could not, however, treat successfully with labour leaders who did not recognize honour and fair play any more than they did the laws of the land. Now that reason has been reinstated among the workmen, we shall look to them to meet the management of the British Empire Steel Corporation half way in the effort to make collieries and mills the centre of a prosperous community, and to make Nova Scotia bulk large in the iron and steel industry of the world.

THE A. I. M. M. E. EXCURSION

Four weeks from today the summer excursion of the American Institute of Mining and Metallurgical Engineers will be in progress through the mining districts of Northern Ontario, with Quebec still ahead. It will be an important occasion for the mining camps visited, and an interesting occasion, we are confident, for the visiting miners and metallurgists. The unique nickel field at Sudbury, the outstanding silver camp at and about Cobalt, the gold district further north that already holds the interest of mining men and investors in many countries, and the famous Quebec asbestos region — all these will be fruitful subjects of investigation as the tour proceeds. In each camp arrangements are in progress, not only to entertain the excursionists, but to hold a technical session discussing the local geology, mining and metallurgy that will be worthy of each of these prominent mining centres. These arrangements are in the hands of local committees.

For this occasion the *Canadian Mining Journal* has enlisted the aid of a number of prominent Canadians connected with the mineral industry in preparing a special number designed to aid the visitors in their studies of our mines and methods. The object has been to supplement the information and ideas that will comprise the technical sessions at the various mining centres, and to draw attention to, and stimulate discussion of, points that otherwise might be overlooked, as well as to present, from competent au-

thorities, summary accounts of the mineral areas. This number of the *Journal* will be issued on August 17th, and will be placed in the hands of the excursionists on their arrival in Toronto on August 20th.

The Canadian mining fraternity will welcome the visitors not as strangers or foreigners, but as acquaintances and friends. In spite of the international boundary, the fortunes of mining men on both sides are closely connected, and there has been, to an extent that few of us realize, an interchange of technically trained personnel in the mining and smelting centres. Thus the present excursion will serve, not only to inform our confrères from the United States about the facts of our present mining industry and our hopes for the future, but also to provide additional reason for the feeling of good-will for which our international relations already are notable.

A PROBLEM FOR MINERS

Periodically we point, in these pages, to the fact that the mining industry must be the pioneer to open up a large part of the unsettled portions of Canada. We have evidence round about every established mining camp or colliery district of the close inter-relation of mining, settlement and industry in general. At Timmins, Ontario, we find a town of 12,000 inhabitants that has grown with the two great gold mines, Hollinger and McIntyre, and a surrounding settlement on the land that will extend for many years to come. So long as the mines last, the townspeople are assured of occupation and the farmers in the surrounding countryside are provided with a market more than ordinarily profitable. The farms will, in the long run, produce more material for human consumption than the mines; but their settlement has been induced in the first place by the working of the deposit found by the prospector in the midst of the forest, far from the railway.

The point we wish to remark particularly today is that, to a very large extent, it is up to the mining men of Canada to solve the vexed problems of immigration, of a national railway system that causes a huge annual deficit, and of a national budget that allows our national debt to soar to a dizzy height.

Consider immigration. While we discuss coaxing a few thousand Britishers to our shores, the United States has to put down the bars against Britishers, the monthly quota having been filled. Our climate does not frighten these people. We can offer them cheaper and better land. We cannot offer them so good a chance of making a living. Our own people are swarming across the border, because "times are good" there while things are dull on this side. If we had the right conditions here, Canada would draw the crowd instead of her neighbor.

We would judge that the development of the mining industry offers the surest, soundest and most rapid means of inducing the development and settlement of our country. Unfortunately for our fertile prairie land, the new gold field will provide a market far removed; but the Great Clay Belt of Ontario and Quebec, more difficult of settlement, will reap a substantial benefit from the mines along its southern border. Once cleared and established in production, this northern area will rival the more southernly areas in Ontario and Quebec, and the trunk lines of railway that intersect it, supplied with a network of "feeders," will be an asset to the national exchequer.

In a number of other localities throughout Canada, similar examples are to be found. In each case the first move is up to the prospector and the miner. We cannot hope for a mineral development either on the scale or with the rapidity of that which peopled the United States in such short order. But we can and must find and put to use our mineral treasures so as to keep our young men employed profitably at home, attract more people to our shores, and provide good markets for our farmers and manufacturers, thus to build up a well-rounded prosperous, and, as nearly as possible, self-contained national community.

"PLATINUM ASSAYS AND PLATINUM PROMOTIONS"

This is the title of a report (serial number 2496) just issued by the Bureau of Mines in Washington. Its stated purpose is to warn the public against mine promotions based upon assay returns that are either honestly mistaken or deliberately falsified. Forty four samples from various states were examined. One was found to contain platinum sponge, and another platinum foil and wire — obviously salted. The assayer's name, where available, is given in each, with the amount of platinum he reports. In no case was platinum found in these samples, apart from those obviously salted. The report includes as well a direct warning to the public against any promotion based upon reported platinum deposits in the United States; the search stimulated by the needs of the war period failed to reveal any appreciable natural resources of platinum in the United States.

This unequivocal and forceful official statement from the Bureau of Mines is, evidently, part of the determined and concerted effort of public officials in the United States to check the issuance of fake stocks, particularly mining stocks, whereby the public are mulcted of millions of dollars annually. It is principally by means of the public mails and through the pages of newspapers licensed to serve the public that the stock-jobbers do their dirty work. It is extremely difficult to draw a hard and fast line between legitimate speculation on the one hand and wild and dishonest schemes on the other; yet it is not at all difficult to class certain promotions in the latter class.

The Bureau of Mines in Washington has now undertaken what we hope will become firmly established as a custom, not only in the United States, but in Canada. Genuine mining authorities, in both countries, are far too chary about exposing and denouncing publicly the unwise or dishonest ventures that, assuming the name of mining, come within their notice. Public authorities, in particular, by virtue of their position in the public service, are under obligation to aid and to educate. On occasion our Canadian Departments and Bureaux of Mines have been outspoken about such frauds or ill-conceived undertakings. We look forward to the time when they will range themselves more actively on the side of those who would abate the present nuisance and wastage of capital.

HYDRO-ELECTRIC POWER AND MINING

The natural resource in Canada that is receiving most attention today is water-power. Its development is in the hands of a group of engineers and financiers who are making the most of a wonderful opportunity. Hydro-electric power is being developed not only to meet the present needs of industry and of urban communities, but is also being provided as an inducement for the establishing of new industries. By virtue, to a large extent, of cheap power, a number of localities in Ontario and Quebec have become veritable hives of industry, and eastern Canada promises to become one of the world's important industrial centres.

At some time in the not distant future, those interested in the development of hydro-electric power will find themselves searching for opportunities for its further use. At present markets for power are not so difficult to find, and even when not ready-made, there are many cases in which such markets can be created by means of a little well-applied effort. Within a measurable term of years the market for electric power will have become saturated. Then will come an opportunity for the mineral industry. Mines themselves consume comparatively little power; but to work up certain minerals into merchantable form, enormous quantities of electric power can be used profitably. Already electrolysis, electrothermic reduction and electric furnace refining are responsible for a large part of Canada's finished mineral products. Calcium carbide and acetylene, and the acetic acid and other products derived from it; artificial abrasives; high-grade alloy steels; refined nickel, copper and zinc; ferro-alloys; artificial graphite — these are a few of the important industrial materials already made from minerals by aid of the electric current. Their number is increasing constantly, and electro-metallurgy and electro-chemistry offer fields for research whose importance is vast, but difficult to gauge. The newest of the branches of chemistry and metallurgy, they have made wonderful strides during recent years, with promise of continuous and still greater advances in the future.

Those interested in the mineral industry and those others interested in hydro-electric power should "get together" more closely, for their mutual benefit. At present there is no close *liaison* between the two groups. The miner searches for markets for the raw materials he produces, and the producer of hydro-electric power looks for wheels to turn or furnaces to heat. Between them is a gap, to be bridged by the metallurgist and the chemist, and most of all by the researcher in applied chemistry .

This is a problem of today, as well as of tomorrow. It is worth the attention of the best technical men and the keenest business men of both the mineral and the water-power industries.

COBALT OLD AND NEW

Here once of old the bears plunged through the brake,
(Plunging, and then the break, show still they're here.)
And moose and caribou their haunts did make.
(Here many still find fortune hunting dear.)

Here once red Indians did their camp-fires strike,
(To-day each new-made strike fires all the camp.)
And on the warpath, seeking gore, they'd hike.
(Now, seeking ore, what throngs their footprints tramp!)

Coureurs des bois deep-laden plowed the drifts,
(In drifts to-day with other lodes men vie.)
The rare furs, bringing, fit for kingly gifts.
(Here also now at times the fur doth fly!)

Here soldiers of the king wrought valiant deed,
(All deeds here now are with suspicion viewed.)
For which to some were titles well decreed.
(O'er title now what peck of trouble brewed!)

Chill, bleak this land — Our Lady of the Snows,
("Cold feet" and "frosts," now's lacking neither thing.)
"A nipping and an eager air" here blows.
(And nipped are many by this Nip I sing!)

(Editor's note. — The above verses, which circulated through the press in 1907, the first boom year at Cobalt, apply as well today, with the exception of the last phrase. Many will remember the wild gyrations of various of the Cobalt stocks on the markets, said to be due to the manipulation of "insiders" — a custom not yet obsolete. However, if we change the name in the verse, we spoil the rhyme; so it is best to let it stand as a monument to the departed glory (market-wise) of Canada's greatest silver mine.)

THE USE OF ELECTRICITY IN COAL MINES

By JAMES A. ERSKINE*

During the past forty years, no department of science has made greater progress than that concerned with electricity and magnetism. The use of electric light and power in mines has caused a most astonishing change in the mining industry. In the year 1880 the first arc lamps that were employed for regular work at any colliery, and the first electric light of any kind underground, were installed at the Mardy and Cymmer Collieries in England. The first use of electric power in mines was at the Trafalgar Colliery in Forest of Dean, England, in 1883, where it was installed for driving a pump. Thirty years ago there were only four electric power installations in the mines of Britain, and at that time only forty-two collieries had adopted electric light. Of this number twenty were in South Wales, seven in Staffordshire, four in Derbyshire, five in Lancashire, and six in the North of England.

Looking back at those days one wonders at the audacity with which electrical engineers undertook all manner of work, and generally carried it through with a fair measure of success.

An Early Installation

My first experience of mining electrical plant occurred when, as an apprentice, I was sent with an electrical engineer to report on a lighting plant at a colliery. When we arrived at the colliery we found the electrician, or rather the man-in-charge, and were shown two Gramme machines. The tension on the brushes was obtained by a number of bolts, nuts and washers hanging by a piece of string. The machines were simply covered with candle grease. Having asked the cause, we were told that candles were used to give light for starting up. It was noticed there were no lamps in the engine-house, and on asking how they managed after starting, we were informed that these were not necessary, as there was plenty of light from the brushes. After starting up, it could be seen that the statement was quite correct. The mistake in the early days was that the apparatus installed was quite unsuitable for mining conditions. The intention was to make the mine suit the apparatus, instead of the apparatus to suit the conditions of the mine.

However things gradually improved until there were some excellent direct current plants in mines working at 500 volts. Then three-phase current was introduced into mining, and with the installation of these up-to-date plants, the colliery managers began to acquire a knowledge of electrical engineering. But the new motive power and its peculiarities played many pranks during the practical training of some of these men.

A few years ago a young electrical engineer was in charge of a three-phase plant at a colliery. He was obliged to go away one day on business, and that morning about nine o'clock his assistant told the manager that he would have to switch the current off a certain district as there was a "ground" there. The manager exclaimed, "A 'ground' on first thing this morning! Why didn't you arrange to put it on yesterday after the pit finished?". However, practically every colliery in England today has an electric plant, and what a change it has made.

* Electrical Engineer, Dominion Coal Company, Sydney.

Features of Modern Installations

The old belt-driven generator and slow-speed horizontal engine have been replaced by direct-coupled sets, and these in turn are being replaced by turbo-generators of larger size. Another striking feature is the steady increase of pressure. From 500 volts the pressure was raised to 2,000 volts, then to 3,000 volts, and current at this pressure is now taken right into the mine, and transmission lines of 6,000 and 11,000 volts are quite common. To-day some of the colliery electrical plants are equal in extent and perfection to the power stations of our large cities. Enormous strides have been made in the application of electricity underground for pumping, hauling, coal-cutting, conveying, etc. There are many mines where it would be commercially impossible to pump by any other means. Electrical haulages up to several hundred horse-power are now quite common, and small portable haulages are largely dispensing with horses underground.

It is a mistake, however, to put electricity in places underground where the conditions are unsuitable, and this applies particularly, I believe, to coal-cutters. It must not, however, be imagined that electric coal-cutters installed on old collieries will revolutionise them instantaneously. To get results the workings must be laid out on a plan to suit machinery. More coal-cutter failures have resulted from lack of adequate haulage capacity, insufficient ventilation, inadequate supply of power, want of organization in carrying on the work, want of study of roof conditions and other causes, than from defects in the machines themselves. It is here that the mining and electrical engineers must co-operate, each studying the situation from the other's point of view, and by both applying their minds to the work, make the application of machinery a success. Further, having installed the plant and having made all necessary arrangements, the results must be followed up, daily records kept, haulage arrangements made perfect, and an analysis made of all interruptions or sources of delay. This organization must be maintained or disappointment will result.

Good Opening for Further Electrification

There is an all-important factor still to be mentioned, the need of brains — the faculty of imagination, of intelligence applied to industrial problems, and the conception of new ideas. No branch of engineering gives greater scope to man's inventive genius than electricity. It is still in its infancy, although tremendous strides are being made. There is plenty of scope in the mining industry for the exercise of ingenuity and intellect, not only by purely mining men, but also by electrical and other engineers, for there are many unsolved problems in mining.

As to the mining industry itself, a much discussed question always arises as to how we are to improve upon the unsatisfactory position with respect to output per person employed. Those engaged in the electrical industry will be interested to know that one of the most fruitful means by which increased production can be attained is by the greater use of power; and likewise

that electricity is admittedly the most convenient and economical means of transmitting and applying the power so much required.

There is no doubt that the amount of electric power employed per unit of labor in most coal mining districts is much less than it should be. This is at present being brought gradually to a higher standard. In Cape Breton, one example of this is the electrifying on an extensive scale of some of the Dominion Coal Company's collieries at Glace Bay. Those engaged in the electrical industry, therefore, need have no hesitation in preparing for a largely increased demand for electrical plant of all kinds, and in particular electrical manufacturers and engineers are well warranted in considering the needs of the coal mining industry.

Makers of mining appliances will require to have mining specialists whose experience and training in mining conditions qualify them to advise mining engineers on the problems that confront themi. All that is best in mining machinery in other countries must be studied and borrowed for our use. There will be a great demand for all classes of labour-saving devices tending to cheapen the cost of removing the coal from its bed, and placing it in cars at the pit-head.

The Need for Study and Research

In conclusion I should like to add that every mining concern, however small, should have on its staff men fitted by experience and training and gifted with imagination to devote part of their time regularly and consistently to the solution of new problems. Any suggestion, by whomsoever made, should be welcomed. In the multitude of counselors there is wisdom, and one good idea out of a dozen fruitless suggestions will repay a great amount of study. The use of electricity in mines offers a fruitful field for such research.

The head of a company or of department can never afford to neglect details. He should know his business from A to Z. He must put in a great deal of solid spade work. But he should always use the telescope as well as the microscope, taking a broad outlook as well as making a minute investigation. He must exercise his imagination in the search for new ideas for improvement, else he will spend his days like the man in the famous picture, grovelling for coppers with a muck-rake when by looking up he might have discovered the crown of success. One of his guiding stars must be electricity.

There is a lot of truth in the old saying, "Whatsoever a man soweth that shall he also reap". And whether it is applied to work, study or purity of life it helps greatly in laying the foundation of one's character to feel that we shall reap what we sow. There is inspiration in this for the mining engineer and for the electrical engineer engaged in mining.

REVISED STATISTICS ON THE MINERAL PRODUCTION OF CANADA, 1922

The Dominion Bureau of Statistics issued on July 16th, the following finally revised statistics on the production of cobalt in Canada during 1922, and on July 18th, those on gold.

Cobalt

The major portion of the world's supply of cobalt for almost two decades has been derived from the silver-cobalt-nickel arsenides of the Cobalt district.

During 1922, three smelters in Ontario treating ores and residues from this district marketed cobalt oxide, metallic cobalt, cobalt sulphate, cobalt carbonate, cobalt hydroxide, unseparated oxide and stellite (an alloy of cobalt used for high speed tool metals). The cobalt residues from the cyanide process were mainly treated in Canada during 1922 although some of these as well as smelter residues amounting in all to 518 tons containing 173,211 lbs. of cobalt were shipped abroad for treatment.

The cobalt production of Canada in 1922 was 569,960 lbs. which at $3.25 per pound would be worth $1,852,370. These figures were obtained as the total of the metal cobalt contained in smelter products made in 1922 and cobalt in residues exported for treatment, valued at $3.25 which was the average New York quotation for cobalt during the year.

SUMMARY OF COBALT PRODUCTION STATISTICS, 1922

Cobalt ores and residues treated or in process 3,719 tons. Metallic cobalt content of the above (by assay) 536,400 lbs.

	Output of Smelters		Marketed	
	Total	Cobalt Contained	Quantity	Value as reported by smelters
	lb.	lb.	lb.	$
Metallic cobalt	106,274	106,274	109,067	282,602
Cobalt oxide	360,495	252,347	398,697	798,271
Mixed oxide	86,730	39,023	123,605	99,687
Residues exported	A	172,311	1,036,000	156,402B
Total	Quantity	569,960		1,336,962
	Computed value	$1,852,370		

A — Not given; B — Estimated.

Gold

During the calendar year 1922, the gold production from all sources in Canada amounted to 1,263,364 fine ounces, valued at $26,116,050, an increase of 36 per cent. above the previous year. This production has only been exceeded once, that being in 1900 when 1,350,057 ounces valued at $27,908,153 was produced. In the latter year the Yukon placers reached the peak of their production.

The values given below are those reported by the shippers as the total payments received for gold and silver contained in products shipped.

	Quantity tons	Value as Reported
Gold ores and concentrates shipped	74,624	$ 4,859,045
Bullion shipped from auriferous quartz mines		21,257,302 (A)
Bullion shipped by placer operators		1,488,785

A — Includes $209,256 exchange paid.

Production by provinces as shown below includes:

1.—Gold obtained from Canadian gold ores and concentrates treated during the year either in Canada or in other countries.

2.—Gold obtained from Canadian ores which were treated essentially for other metals.

In determining the values, the standard rate of $20.671834 per fine ounce was used.

Provinces	Fine ounces	Computed Value
Nova Scotia	1,042	$ 21,540
Quebec	....	.....
Ontario	1,000,340	20,678,862
Manitoba	156	3,225
Alberta	....	.....
British Columbia	207,370	4,286,718
Yukon	54,456	1,125,705
Total Gold Production of Canada	1,263,364	$26,116,050

The Rio Tinto copper mines made a profit of £996,354 in 1922 as against £[illegible] in 1921.

The Collieries of British Columbia

III. — Vancouver Island Coal Field

By ROBERT DUNN

All Vancouver Island coal comes from mines within a compass of between sixty and seventy miles along its eastern seaboard. At Extension and South Wellington are the collieries of the Canadian Collieries (D) Ltd. Extension is connected by a short spur railway with the town of Ladysmith, where a fine harbor and modern shipping facilities permit the ready and economic handling of the mercantile trade. North a few miles is the city of Nanaimo, the pioneer coal centre of the American Northwest and the home of the Western Fuel Corporation of Canada. In the same direction some seventy miles we find the Cumberland Mines, operated by the Canadian Collieries, with railway connection with Union Bay. Here is duplicated much the same situation as that at Ladysmith, the coal field inland a short distance feeding a land-locked harbour that offers the best of protection to shipping in search of fuel.

Location and Extent of Coal Field

Vancouver Island is about 300 miles in length and on an average of 50 miles in width — not a great area when compared with the whole of British Columbia with its 372,639 square miles; yet its coal mines in 1921 produced almost as much again as all the others of the Province. Up to the present the development has been confined to that section known locally as the Esquimalt & Nanaimo Railway Belt, a strip of land lying along the east coast within whose boundaries are 3,296 square miles. There are those who hold that the seams of the Cowichan region, roughly forty miles north of the city of Victoria, can be economically exploited. That, however, is a question yet to be decided. No serious efforts have been made to solve the issue in regard to which there is much difference of opinion. Certain it is that in the Newcastle and the Comox Districts there are extensive coal resources. To a limited extent these have been opened up by the companies now active, but there are reserves that will keep the wheels of industry moving indefinitely.

D. B. Dowling, of the Canadian Geological Survey, in his "Coal Fields and Coal Resources of Canada" estimated in 1915 that the actual coal reserve of Vancouver Island was 1,178,000,000 metric tons. In the same volume C. H. Clapp, also of the Survey, is quoted and an excerpt from his observations may not be amiss:

"The coals of Vancouver Island are all, so far as known, of Upper Cretaceous age. They are associated with a thick series of sandstones, conglomerates and shales called the Nanaimo series, which were deposited, largely under estuarine conditions, on the irregular, drowned portions of the pre-Upper Cretaceous erosion surface, developed on the metamorphic and granite rocks of the Vancouver range. The deposition took place chiefly off the east coast of the range in the down-warped basin between Vancouver Island and the Mainland, but some deposition occurred in the broad estuaries extending inland from the northern portion of the west coast."

At another point Mr. Clapp says:

"The area which is underlain by workable coal seams is, however, much less than the total area underlain by the Coal Measures, being approximately one third of the latter. Those basins that probably contain workable coal seams are the Koskeemo, which is a portion of the Quatsino Sound basin, the Suquash basin, and portions of the Comox, Nanaimo, and Alberni basins. Of these the Suquash, Comox and Nanaimo basins contain workable coal-seams, which are being mined at present."

Discovery and Early Operations

Coal was first discovered on Vancouver Island in 1835 at a point on the East Coast then called Fort Rupert, north of the City of Nanaimo. Dr. Geo. M. Dawson, at one time director of the Geological Survey of Canada, read a paper before the Royal Colonial Institute in which he said:

"The existence of coal upon the coast of British Columbia was recognized by Dr. W. F. Tolmie, an officer of the Hudson's Bay Co., as early as 1835, but

though small quantities of coal were actually obtained from natural outcrops from time to time for the use of the blacksmiths at the company's posts, no importance appears to have been attached to the discovery. The world was at that time very spacious and the Pacific Ocean was still regarded rather as a field for exploration of navigators than as a highway of commerce between America and Asia. Afterward (in 1849) the Hudson's Bay Company brought out a few coal miners from Scotland and proceeded to test and open some of the deposits."

The Nanaimo coal deposits were seriously exploited from about 1852 and before the close of the following year 2,000 tons of coal are reported to have been shipped, chiefly to San Francisco. The Hudson's Bay Co., under the name of the Nanaimo Coal Co., continued to work the mines until 1861, when they were sold to the Vancouver Coal Mining & Land Co., Ltd. The area in question has been operated without cessation ever since and No. 1 Mine, Nanaimo, notwithstanding frequent reports that its days of production were numbered, still is one of the largest and most consistent producers of the Province. At present it, together with several auxiliary properties, is worked by the Western Fuel Corporation of Canada, the direct inheritor of resources first recognized and exploited by that pioneer Canadian corporation, the Hudson's Bay Co.

Mines of Western Fuel Corporation

The mines of the Western Fuel Corporation in 1921 had an output of 566,034 tons which, it will be noticed, is a substantial part of the total provincial production for the year, which was 2,483,995 tons. Underground and surface development have kept pace with requirements. Steam is the motive power for almost all operations. At No. 1 there are two Babcock & Wilcox water-tube boilers and at least ten return tubular boilers, the whole generating upwards of 2,000 h.p. There also are two large 2,500 cubic foot Canadian Ingersoll-Rand cross-compound compressors used to provide air for mining machines, winches, etc. A 250 KW generator supplies power for the electric locomotives used for transportation on the main level. A 30" x 60" steam hoist with a 15-foot drum is another part of the equipment. At Protection Shaft, Protection Island, there are six 150 h. p. boilers, two compressors similar in type to those of No. 1, a hoist of the same dimensions as to cylinders but with a 12-foot drum, used only in the lowering and hoisting of workmen, and a forced draft fan which ventilates the north side of No. 1, the return being the shaft on Newcastle Island. At No. 1 there is a Sirocco fan for the ventilation of the south side of the mine, the return being by No. 2 shaft alongside. An auxiliary hoist and fan are installed at Newcastle Island, which can readily be put into operation in the event of a break-down at Protection. All coal is brought out at No. 1 shaft and screened and prepared there. No. 1 level at present is some three and one-half miles in length and, while a considerable part of the mining now is submarine, much of it is going on beneath the islands lying in and around Nanaimo Harbour.

The measures of the Nanaimo field consist of three seams known as the Douglas, Newcastle and the Wellington. The first is the uppermost and the last the lowest. At No. 1 Mine the Douglas and Newcastle seams are being exploited. The "Wakesiah," and the "Reserve" Mines of the same Company are being worked on the Wellington and Douglas seams respectively. The "Wakesiah" was opened about two years ago and at present the output averages about 400 tons a day. This mine is two miles from Nanaimo. The contour of the field is irregular, and haulage, which is taken care of by five winches driven by compressed air and supplemented by horses, is both difficult and costly. There are two shafts sunk to a depth of 320 feet and coal is hoisted from No. 2 shaft, steam being furnished by two boilers of 160 and 140 h.p. Ventilation is produced by a single inlet Murphy fan, driven direct. The mine is damp and free from coal dust. The "Reserve" is in the Cranberry District, five miles south of Nanaimo, and the coal is reached by two shafts at a depth of 955 feet. The seam varies in thickness from 1 to 20 feet and the coal is soft with a fairly strong roof. A pair of 90-inch Sirocco fans take care of ventilation, being capable of producing 140,000 cubic feet of air a minute against a 3-inch water gauge. There are twelve compressed-air hoists and the surface plant consists of four return tubular boilers, each 208 h.p.; a hoisting engine 30 x 60 inches with 12-foot drum, and another 24 x 48 inches with 12-foot drum, each having an automatic overwinding device; one cross-compound Canadian Rand compressor and an Ingersoll-Rand compressor, with a capacity of 22,000 cubic feet of air a minute at 120

Ships Bunkering at the Docks of the Western Fuel Corporation, Nanaimo, B.C.

revolutions. An electric generator supplies light above and below ground and there is a three-car self-dumping tipple with shakers consisting of two screens, 1½ inches and ¾ inch respectively, a picking table, and nut and cross conveyors driven by a small steam engine.

Coal Washery and Oil Flotation Units

Experiments in oil flotation have been carried on by the Western Fuel Corporation, Canadian Collieries (D) Ltd., and the Granby Consolidated Mining & Smelting & Power Co. In this connection recent improvements in the washery plant of the first named are interesting. All the coal of the company's various mines is assembled at a central point on the water front in Nanaimo where the bunkers, wharves, car-ferry ship, and blacksmith, machine and carpenter shops are located. There it is screened and washed preparatory to marketing. Recent changes in the washery involved the discarding of the jigs and the substitution of four Deister coal concentrating tables and the installation, as an auxiliary, of the Peterson Oil Flotation Plant. The latter is designed to treat material from the refuse dump and the discard from the picking tables in the washery. The material in the refuse dumps is carried into the plant by a paddle conveyor, which delivers it to a trommel-screen; the oversize passes from the trommel by gravity down a launder to an 8-foot Hardinge ball-mill; the undersize passes by gravity into a screw classifier, the oversize from which passes by gravity to two Diester coal-concentrating tables. These tables give three products—coal, middling, and rock. The undersize or overflow from the screw classifier is carried by gravity to a battery of six Peterson flotation cells; the flotated product from two of these cells is clean coal and from the other four middling. The coal from the flotation cells passes by gravity into a settling tank 30 feet in diameter, from which the dewatered fine coal passes to a paddle conveyor, by which it is carried to railway cars ready for market. The middling from the flotation cells passes by gravity along a launder to a bucket elevator near the ball mill, into which the overflow water from the settling tank is also discharged. The bucket elevator discharges into a launder, along which the material passes by gravity to the trommel screen already mentioned and is subjected to the same series of treatments as has been described. The coal and the middling concentrate made on the Deister tables are carried by gravity to a second screw classifier near the settling tank, so that the overflow from the classifier can be discharged into the settling tank, while the fine dewatered coal is carried to the paddle conveyor, which delivers it to the railway cars. One of the advantages of this treatment is that the slack can be more thoroughly picked over on the picking tables and a cleaner product made because practically all the carbon in the refuse is saved later in the concentrating washer.

Edison safety lamps are used almost entirely in the mines of this Company. Speaking generally, the plant is of the most modern description and the mining practice similar to that in most present-day bituminous coal fields. The pillar and stall system is that most used. Where conditions make it an economic necessity, the longwall method is adopted, this being so in a section of No. 1 Mine. G. W. Bowen, the vice-chairman of the Company, and John Hunt, general superintendent, are the active heads of the concern. Robert Laird is Mine Manager No. 1 Mine, Robert Henderson, at the Reserve, and William H. Moore at the Wakesiah. The Harewood, another of the group of subsidiary mines of this Company, may be passed with a word because it was abandoned early in January last, its long career as a producer at an end. With a capable and loyal staff, and by virtue of a broad and considerate policy, the Company maintains cordial relations with its employees, and the industry has flourished, without serious interruption, for scores of years.

(To be continued.)

BRITISH MIGRATION

An official American observer in Western Europe discusses unemployment in Britain thus, in *Commerce Reports:*

Great Britain has made enormous strides since the armistice along financial, commercial, and industrial lines. Unemployment is now the basic difficulty. Although at the present time industry is working almost to capacity, the live unemployment registers show a million and a quarter persons out of work, and, as a matter of fact, it has been estimated by certain experts that the actual total unemployment in that country is now almost one and three-quarter millions.

This problem in Great Britain seems to be based on several factors aside from the one commonly mentioned—that the population is growing beyond the industrial capacity of the country to support it. During the war women and minors were employed in various industries and are still employed to a considerable extent. A large proportion of the pre-war idle class has been compelled to seek productive employment. Much of the land that was plowed up during the submarine blockade has been allowed to go back to pasture, and surplus farm laborers are also drifting into the ranks of the unemployed in a steady stream. All these causes together have their effect upon the present situation.

There have been considerable fluctuations in the unemployment situation in this country since the armistice. In 1919 and the first part of 1920 the demobilization of troops, together with the shutdown of munition works, increased the number of unemployed to a great extent. During 1920 these persons were steadily employed in industry, but in 1921, owing to the widespread business depression, unemployment, which had dropped to less than a million, went over two million in midsummer. There has been a continual but slow reduction since that time with the exception of the winter months of 1921-22 and 1922-23.

Opinions differ considerably as to the remedy for this situation. Some believe that it will be corrected in due course of time by new commercial and industrial developments, but a large percentage of expert opinion seems to indicate that the only remedy is emigration. The matter may be brought up at the Imperial Economic Conference next fall; and if so, there will be the inevitable disagreement between Great Britain and the Dominions as to the type of emigrants to be sent out. Efforts are already being made to dispose of certain portions of the surplus population, but co-operation between the Mother Country and the Dominions will be necessary in order to execute such a program on a large scale.

COPPER PRODUCTION IN ALASKA INCREASING

The copper production of Alaska in 1922 was 77,967,819 pounds, valued at $10,525,655, compared with 57,011,597 pounds, valued at $7,354,496, in 1921, according to the U. S. Bureau of Mines. The production in 1922 came from one mine in the Ketchikan district, three on the Chitina district, and one in the Prince William Sound district. These figures are taken from the annual report of the Geological Survey on Alaska mineral resources, now in preparation.

Field Work of the Staff of the Victoria Memorial Museum, 1923-4

By WILLIAM McINNES, Director

The Victoria Memorial Museum, or National Museum of Canada, carries out original scientific investigations on the wild animals and birds of Canada, its botany and the aboriginal Indian tribes, in addition to maintaining at Ottawa a National Museum. In the museum are displayed collections and specimens illustrating the natural history of Canada and its anthropology and archaeology.

In order that the subject of bird and wild animal protection and conservation may be intelligently and effectively dealt with by the State, the life histories of the birds and animals must be thoroughly known, and this subject is now principally engaging the attention of the biological staff. The botanist is dealing with the plant life of Canada in a similar way.

Canada recognizes a moral obligation toward the native Indian tribes, and through the Department of Indian Affairs takes a fatherly interest in their well-being. The scientific study of the origin of the aborigines, their migrations, languages, culture and beliefs is outside the scope of that Department, and is carried on by the Anthropological Division of the Museum. Linked up with the preceding is a study of the Archaeology of the country and this subject will be given attention by two parties, one working in British Columbia and one in Ontario.

A programme of the field work for 1923-4 in detail follows: —

Biological Division — Botany

M. O. Malte, Chief Botanist, National Herbarium, is continuing his survey of the flora of the Ottawa region, covering a radius of about twenty-five miles on both sides of the Ottawa valley in the Provinces of Ontario and Quebec, and extending the explorations in some cases to a greater distance, as up the Gatineau valley. This field work has advanced appreciably the information necessary for the completion of the work on the Flora of the Ottawa district begun by the late Professor John Macoun and James M Macoun. Dr. Malte began the field work with the appearance of the first spring plants and expects to continue it until late in the autumn. Since the 1st of June he has been assisted by H. A. Quackenbush, a student assistant who helped him in the same kind of work in 1922. Mr. Quackenbush will be engaged in the work until September. Several hundred sheets of herbarium specimens have already been added to the collection during the present season.

Zoology

P. A. Taverner, Ornithologist, will have a short season of field work, having remained in Ottawa to complete his work on the "Birds of Western Canada". In the furtherance of this work he expects to spend some time in the field in Alberta in September and October.

Charles H. Young, Senior Collector Preparators, left for Waterton Lakes Park, in southwestern Alberta, about May 1st and has planned to collect birds and mammals in that region, carrying his work further out from the foothill than was done during the preceding season.

R. M. Anderson, Zoologist (Mammalia) is spending the early part of the summer in museum and office work, and is expected to spend parts of August, September, and October in biological collecting in eastern Quebec, and also a short time in Nova Scotia if time permits.

Joseph Rochon, Osteological Preparator, and **Donald MacDonald,** Museum Helper, are expected to spend part of September and October in collecting osteological material in Pontiac county, Quebec.

Clyde L. Patch, Chief Taxidermist and Herpetologist, will collect local fauna and accessories for habitat groups in the Ottawa region. He will also spend one week as instructor in natural history subjects at a Y.M.C.A. boys' camp at Golden Lake, Ontario. D. Blakely, Taxidermist, and Claude E. Johnson, Artist, will spend some time collecting specimens of local fauna and accessories for the museum in the Ottawa region.

J. D. Soper, Junior Zoologist (temporary) will accompany the "Arctic" expedition under J. D. Craig, to Baffin Island, Ellesmere Island, and Greenland, and collect material for the Victoria Memorial Museum, principally birds and mammals, although he will endeavour to obtain some entomological, botanical, and ethnological material as well. His work is expected to be mainly in the Northwest Territories (Franklin district), but some material may be obtained when the ship stops at Hamilton Inlet, Labrador, and in Greenland.

Anthropological Division

Harlan I. Smith is to continue this summer his researches into the material culture, particularly the ethno-botany, of the Bella Coola Indians, including in his work both the aborigines of the village itself and the Chilcotin tribes who descend to the coast there during the summer months. At the same time he is to investigate the archaeological remains in the surrounding district, and make casts of the ancient rock carvings left there by an earlier people. It is hoped that his work will throw some light on the original inhabitants of this region. He left for the field on May 15th and expects to return towards the end of September.

Mr. McIlwraith is also to work at Bella Coola this summer, his special field being the social organization and religious beliefs of the Bella Coola Indians. This work will occupy him about five months, from the beginning of July until the end of November or beginning of December. It will enable him to complete the survey, begun by him last year, of this important and little known tribe.

C. M. Barbeau, left Ottawa on June 16th to continue his work of previous years among the Indians of the Nass River. He expected to spend some weeks near Hazelton, among the Gitshan Indians, then to move lower down the Nass River to investigate some of the neighbouring groups. This work will occupy him about three months. On the return journey he is to make some investigations into the early history of the Indians of the Okanagan valley, and the Stony Indians of the region around Morley, Alberta. He expects to return to Ottawa some time in October.

D. Jenness is to work during the coming winter on the manners and customs and early history of the Carrier Indians of British Columbia. These natives are scattered in small bands on various rivers and lakes during the summer months, but congregate during the winter at different villages along the Grand Trunk Pacific Railway between Prince George and Hazelton. Mr. Jenness will therefore leave for the field about October 1, and station himself at whatever village between these two points seems most favourable. This work among the Carrier Indians represents a new effort on the part of the Division of Anthropology to investigate the rather inaccessible tribes of the northern interior of British Columbia and of the Mackenzie and Yukon valleys, of which the Carriers are the southern most representatives. Mr. Jenness will probably carry on his work around Prince George or Hazelton until the end of the fiscal year.

W. J. Wintemberg left Ottawa on June 15 to investigate some of the archaeological remains in the counties of Simcoe, Gray and Bruce, hoping to discover traces of an earlier population in this part of Ontario different from the inhabitants of the prehistoric Roebuck village, excavated by him years ago. This work will occupy him until September 4. He will then make an intensive exploration of a prehistoric village in Middlesex County, returning to Ottawa about October 8.

Dr. E. Sapir, Chief of the Anthropological Division, left for Camp Red Cloud, Pennsylvania, on June 1st, to work with two Alaska Indians at present living in that place. One of these Indians came from Anvik, near the mouth of the Yukon river, the other from Fort Yukon, near the Alaska-Canada boundary. Their dialects differ considerably from one another, but both belong to the group of languages spoken throughout the whole of the Mackenzie valley area in Canada. Last year Dr. Sapir discovered that some of these languages, notably the Sarcee dialect spoken near Calgary, have the peculiarity of possession tone, like Chinese, and his work this summer with the Alaskan Indians aims primarily at determining whether this peculiarity prevails throughout the whole of northern Canada and Alaska, and whether it corresponds in any way with the tone of Indo-Chinese languages. He expects to carry on this work at Red Cloud Camp until the end of August.

MINES BRANCH SUMMARY REPORT

The Summary Report for 1921 of the Mines Branch, Department of Mines, Ottawa, was published recently. The interval of 18 month between the end of the work described and the date of publication of the report would be a more serious matter were it not for the fact that the results of a number of the 1921 investigations have been made public already in bulletins issued by the Director and in papers published by technical societies and periodicals. If the long delay in issuing the complete Summary Report should continue as at present, it might be of value to the Mines Branch, as well as to the technical public, if the practice of making prompt, informal reports were extended systematically to cover the major part of the investigations made.

Calcite. — H. S. Spence reports on an occurrence of calcite in the north of Frontenac county, Ontario, which is 96.75 per cent. calcium carbonate. It is a vertical vein or band, 90 feet wide at one end, at least 850 feet long, and 65 feet wide at the other end. Mr. T. B. Caldwell has been shipping calcite from it to the United States, to be ground and used in paints and for similar purposes. Mr. Spence describes briefly also the Derry quarry of the M. J. O'Brien Company, in the Buckingham district, Quebec.

Alkali Deposits of Western Canada.—L. Heber Cole describes deposits of sodium sulphate and magnesium sulphate examined during the field season in Alberta and Saskatchewan. Sodium sulphate, or salt cake, is used in making sulphate pulp and in making glass, as well as in the refining of nickel. In the hydrous form (Glauber's salt) it is used in tanning, in dyeing and as a medicine. Magnesium sulphate (Epsom salts) is used in the cotton industry, in dyeing, for certain agricultural purposes and as a medicine. Some of the deposits are being worked.

Oil-bearing Shales. — S. C. Ells examined outcrops of shales of Cretaceous age in Manitoba and Saskatchewan that might be of commercial importance. He found all these to be too low in petroleum and nitrogen content to be of present economic interest. Mr. Ells also summarizes the occurrences of oil shale in Canada.

Natural Gas. — R. T. Elworthy describes the natural gas supplies of Canada, so far as determined, and discusses their possible use as a source of helium, gasolene, carbon black and other products. In the following section he points out the possibility of treating natural gas chemically in such a way as to produce methyl alcohol and formaldehyde.

Bentonite. — E. S. Thompson and A. Sadler have made a laboratory study of this mineral, comparing it with American occurrences of bentonite. Complete analyses of six samples of Canadian bentonite show silica from 54 to 70 per cent. and alumina from 20 to 14 per cent., with 8 to 12 per cent. water and minor amounts of other ingredients. The bentonite absorbs up to five times its weight of water. Its chief use has been as a filler in paper manufacture, and various similar uses are suggested.

The work of the Ore Dressing and Metallurgical Division is summarized by W. B. Timm, chief of the division, and described in detail by his assistants.

Low-Grade Copper Ore from Anyox. — Experiments made by R. K. Carnochan and C. S. Parsons show that this ore is amenable to flotation, which yields a good grade of concentrate and gives a high recovery. Experiments were conducted on both a small and a large scale, using a carload of ore.

Flin-Flon Complex Ore. — C. S. Parsons and R. J. Traill, who have examined the diamond-drill ores across the high-grade portion of the Flin-Flon deposit, show by microscopic examination that the three sulphides of copper, zinc and iron are intimately mixed, but can be separated satisfactorily by grinding to 200 mesh. They can be separated by selective flotation; but as the gold and silver values ($2.00 per ton) are distributed through all three sulphides, it is not likely this method will pay. Roasting and leaching tests indicate good recoveries of copper and zinc; but the tailing would require further treatment to recover the precious metals. Pyritic smelting to obtain copper matte containing the gold and silver is the method indicated as most easily feasible for treating this ore, the zinc being slagged off.

Graphite. — C. S. Parsons treated a sample of ore from the North American Graphite mine, Buckingham,

Que., and found that high-grade products and a good recovery were made by flotation, following practice of already established in the laboratories and applied in the mill of the Quebec Graphite Company.

Lead-Zinc-Silver. — C. S. Parsons and R. J. Traill treated both carbonate and sulphide ores from the North Star mine, Kimberley, B.C. After the carbonate ore had been treated with sodium sulphide, both were found to be amenable to selective flotation, giving good recoveries.

Asbestos. — R. K. Carnochan mentions that the "cyclone" and "jumbo" fiberizers are costly as to power consumption, maintenance and repair, and destroy the long fibres unduly, and shows that dry crushing in a ball mill gives a satisfactory result. It is not possible to compare this result with that of standard practice, as there are no data available of the latter.

Nickel-Copper. — C. S. Parsons has indicated by tests on low-grade Sudbury ore that flotation will give a fairly high-grade copper-nickel concentrate, with a good recovery of values from the ore.

Garnet. — Two samples of garnet rock from Bancroft, Ont., gave good recoveries on the Wilfley table, after crushing and classifying, giving 7.9 and 24.1 per cent. recovery, respectively. A larger shipment from Depot Harbour, Ont., gave 14.7 per cent. recovery in various sizes by tabling, and suction during the crushing gave a ground mica product that promises to be of value.

Brass.—Tests by C. S. Parsons show that a high-grade product, suitable for re-melting, can be made by crushing brass foundry slag and sweepings and putting it over a Wilfley table.

Gold. — Tests on samples of ore from Rice Lake, Manitoba, have been examined by R. K. Carnochan and a suitable method of treatment recommended.

Molybdenite. — Four 200-pound samples of molybdenite ore from the vicinity of Wilberforce, Ont., and a sample from near Masham, Que., gave excellent recoveries and high-grade concentrates by flotation.

Euxenite. — Three-quarters of a ton of feldspar containing the radium-bearing mineral euxenite was received from a feldspar quarry near Maberley, Ont., and clean concentrates by gravity equal to 3.67 per cent. of the total were made by R. K. Carnochan. The loss in treatment was 10.23 per cent.

The work of the Chemical Laboratory is reported on by H. C. Mabee, chemist in charge, and represents a varied lot of determinations of samples received from all quarters of Canada.

Fuels and Fuel Testing. — The work in this division, under the direction of B. F. Haanel, includes experiments by J. H. H. Nicholls and Harold Kohl on lignite carbonization, an investigation of kerosene oil and another of cod liver oil as a lubricant, by P. V. Rosewarne, and an investigation of oil shales by S. S. Swinnerton.

Clay. — For the Ceramic Division, the late Joseph Keele has reported various tests of clays sent to him for examination, and draws attention to some occurrences of pottery clay of industrial importance. He also discusses the working of stony clays, and records the progress of the pottery industry in Canada.

Kiln Scum. — During 1921 a brick company at Ottawa were troubled much with kiln scum. Mr. Keele found that this was due to soluble sulphates contained in the shale used. He made some tests that showed that a small admixture of barium carbonate, three [illegible] 1,000 bricks, prevented this effect by turning the soluble sulphates to insoluble barium sulphate. This was applied successfully in practice in the brickyard, completely preventing the scum.

Pottery. — Mr. Keele draws attention to the excellent opportunity there is in certain parts of Canada for making pottery and table ware of the heavier varieties.

Road Materials. — The systematic examination of gravel pits and other deposits of road-building material was continued during the year by Henri Gauthier, samples being tested in the laboratory.

Peat. — The volume concludes with the report of the Joint Peat Committee for 1921.

INDUSTRIAL ITEMS

Canadian Link-Belt Company Limited have changed their name to Link-Belt Limited, explaining that the old name was too long and full of repetition. Link-Belt Limited are well-known as manufacturers of original Ewart link-belts, socket wheels, conveying and elevating machinery, locomotive trains, electric hoists, etc. Their Toronto address is Wellington and Peter Streets, and at Montreal they are located at 10 Gauvin Lane.

Turbro Waughoist, Model 300, a new product of the Denver Rock Drill Manufacturing Co., is completely described in their new bulletin, number 300. It is a heavy double drum portable hoist designed primarily for scraping, operating on the well-known principle that is the basis of Turbro Waughoist construction. It develops 10 horsepower at 50 pounds air pressure and weighs 495 pounds.

Worthington Pump and Machinery Corporation have put on the market recently a new type of deep well pump, which uses one or more impellers much like a ship's propeller to elevate the water or other liquid. The efficiency, capacity and operating economy of this new pump are said to be far in advance of any deep-well pump now in use.

Diesel oil engines are now being installed quite generally to provide power at mines. Lammers and Maase, who handle the well-known Polar Diesel Engine, have calculated that it provides power just as cheaply, or more cheaply, than hydro-electric power in Northern Ontario. Their figure for a 400-horsepower engine is $30.00 per horsepower year, with fuel oil at 12 cents a gallon.

The Robins Conveying Belt Company's "Handbook of Conveyor Practice" is a 96-page book full of useful information about conveying problems and their solution. Belt conveyors and accessories are the main issue; but ore bridges, ship loading installations, ore bedding systems, car dumpers and special conveyors in industrial plants are also part of the Company's products.

Messrs. Glenfield and Kennedy, Ltd., Kilmarnock, Scotland, have just placed on the market a new pressure meter for the measurement of oil and other liquids. The meter is of the displacement type, is made in standard sizes from 3-inch to 8-inch bore. The 6-inch size handles 16,000 gallons of oil per hour, with an overload capacity of 25,000 gallons. It is simple and rugged in construction and accurate in measurement.

Bauxite to the extent of 8,905 tons was shipped to the United States from British Guiana during the first quarter of 1923.

BOOK REVIEWS

THE ELECTRIC FURNACE FOR IRON AND STEEL, By Alfred Stansfield. McGraw — Hill Book Co., 370-372 Seventh Ave., New York — 450 pages, illustrated. Price $5.00.

In this volume, just through the press, Dr. Stansfield brings up to date part of his book, "The Electric Furnace," first published in 1907 and re-written in 1913. The use of the electric furnace has made such strides during the last ten years that now it would serve no useful purpose to include a discussion of all its uses in one volume. The present volume is concerned exclusively therefore, with its use in the metallurgy of iron and steel. A second volume will describe its uses in other branches of metallurgy.

The volume is divided into three parts. Part I describes briefly (41 pages) the history of the electric furnace, the elements of iron and steel metallurgy and the essential points of the electrical supply required for this purpose. Part II deals comprehensively with electric smelting of iron ores by various methods, and the production of ferro-alloys. Part III describes the manufacture of steel and the important types of electric furnace used for this purpose. In each part the fundamental principles involved are carefully explained, and the historical development of method and apparatus is given adequate attention. The volume is concluded by an unusually thorough, though brief index — a section that too often receives only the fag end of an author's attention.

A chapter that will attract much attention at present is that with the caption, "Indirect Electric Smelting of Iron Ores," which deals with the production of sponge iron . Dr. Stansfield has done a good deal of research into this method. One can gather, from his continued and active interest in this subject, that he has hopes that a commercially successful process will be evolved. Fundamentally such a process offers a means of producing iron and steel more cheaply than in the blast-furnace, and is particularly adaptable to conditions in certain parts of Canada.

This book promises to be, in the field of electric iron and steel, what Dr. Stansfield's former book has become for the electric furnace — a standard text-book and book of reference. We can discern in the present volume the same qualities of thoroughness, balance and unequivocal statement that have made the first book so valuable.

A TEXT-BOOK OF ORE DRESSING, By S. J. Truscott — MacMillan and Co., St. Martin's St., London, and MacMillan Co. of Canada, St. Martin's House, Toronto, Ont. — 680 pages — fully illustrated. Price $12.00

The author of this compendious volume is professor of mining at the Royal School of Mines in London, and the book is a result of his teaching and practical experience. It is designed as a text-book, as well as a general work of reference. It deals with the metalliferous ores particularly, and will be followed by an additional volume dealing with coal-washing and the dressing of non-metalliferous ores.

The author devotes a large part of his space (pages 389 to 513) to flotation, which is much in proportion to the present important position the principle of flotation holds in ore-dressing. This section of the book makes it particularly valuable.

The arrangement of the various sections is systematic and consecutive. "Comminution", including crushing and grinding, is followed by "sizing", on screens and in water. "Water concentration," and "flotation concentration" are major sections, followed by magnetic, electrostatic, pneumatic and centrifugal separation. "Heat treatment," including drying, calcining and roasting comprises a chapter, as well as "the control of operations," involving sampling and assaying. A short final chapter describes the application of the principles elucidated and the mechanisms described in the book, as ore-dressing systems and plants.

An author of olden time used to dedicate his work to a benefactor; nowadays he usually addresses a friend. Mr. Truscott has made himself unique in his dedication — in a way we shall leave the reader to discover.

GRAPHITE, (1913-1919) — Imperial Mineral Resources Bureau, Imperial House, Kingsway, London, W. C.2. — 57 pages. 1s 7d post free.

As indicated in this report, the British Empire is in a satisfactory position in regard to the mineral graphite. For long Ceylon has been pre-eminent for its high-grade graphite, which has been the favourite with the makers of crucibles. In view of recent reports that the deposits in Ceylon are approaching exhaustion, it is interesting to note the conclusion that low prices only are the cause of the diminished output, and "that there are still large reserves of graphite available if costs can be reduced to meet market conditions." In 1913 Ceylon provide 28,540 long tons of graphite in a world's total of 131,245 tons. In 1920 the figure is 9,205 tons out of 101,301 tons.

Elsewhere in the Empire, Canada is outstanding on account of the large reserves of graphite in the Buckingham district of Quebec and in Lanark and Haliburton counties in Ontario, as well as the unique Black Donald mine in Renfrew county, which has provided the larger part of all graphite mined in this country. The production was 1,930 tons in 1913, reached a peak of 3,531 tons in 1916, and fell to 837 tons in 1921.

The good market during the war stimulated a small production of graphite in India and Australia, but this has declined again.

Apart from the former territory of Austria, which used to be the world's largest producer of graphite (mostly amorphous), Germany is the world's largest producer (again largely amorphous graphite). Since 1908 Madagascar, which is underlain mostly by ancient crystalline rocks, has become a serious competitor with Ceylon in the higher grades, with a maximum of 34,000 tons in 1917. Japan has important deposits in Korea, a large part of the product being shipped to the United States. There are other deposits of lesser importance, well distributed throughout the world.

STATISTICS, 1919-1921 — Imperial Mineral Resources Bureau.

The volumes on Copper, Iron and Steel, and Lead in this useful statistical series have now been issued.

SPINEL

This mineral sometimes occurs in fine ruby red crystals of value as gems. While the color is very like that of the true ruby, the shape of the crystals easily distinguishes the two minerals. True ruby is hexagonal in form, while spinel ruby is usually in octahedrons of the cubic system. Blue spinel resembles sapphire in color. Fine blue spinel crystals have been found in Daillebout, Quebec.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

Argonaut. — After a number of delays the Argonaut mill was finally put in commission the first week of July, and is treating between 50 and 75 tons a day. The mill has a capacity of 200 tons a day, and the company will gradually increase the capacity to this figure.

Kirkland. — Underground work at the Bidgood has been stopped and it has been decided to carry on further exploration work by diamond-drilling. It is understood that the Tonopah Mining Company is negotiating for a working option on control.

The Kirkland Townsite Gold Mines has been taken over by the Anglo Canadian Explorers Limited, of London, England. The latter company is a subsidiary for John Taylor & Sons, who will proceed with active development. A shaft will be sunk to a considerable depth, and exploration work will be carried on underground. The property is well located and is thought to have very good chances.

During the month of June the Teck-Hughes produced $103,000, which is one of the best months in the history of the company. Underground developments continue favorable and three new levels, the 8th, 9th and 10th, are now being operated.

Lake Shore is cutting a station at the 800-foot level, and will shortly start development work from this depth. The No. 1 vein came into the shaft at 750 feet, where the grade of the ore was higher than at 600 feet. It is stated that at the 600-foot level 1,900 feet of drifting west of the shaft was all in ore with the exception of 50 feet. Good progress is being made with the enlargement of the mill, and it is hoped that 300 tons a day will be treated this fall.

Underground mining work has been stopped at the Kirkland Gateway, and the company will concentrate on diamond-drilling from the 350-foot level.

Cobalt. — During the month of June, Nipissing mined ore of an estimated net value of $181,942, and shipped bullion of an estimated net value of $98,791, silver being estimated at 63½ cents an ounce. The low-grade mill treated 6,372 tons and the high-grade plant 179 tons, while the refinery shipped 151,882 fine ounces of silver. There were no new developments underground during the month, but stoping operations continued to be satisfactory.

Work has been stopped at the Genessee property and an effort will be made to raise fresh funds to continue work below the 350-foot level, where some good ore was encountered in a winze.

Underground operations are under way at the old Provincial Mine and a small amount of high-grade has been encountered in stoping operations. The company proposes to break milling ore and to start shipments in the fall.

A new vein has been cut in a crosscut north of the shaft on the Colonial property, which is controlled by Continental Mines. The crosscut is on the 930-foot level, and the vein is understood to carry substantial milling values.

Gowganda. — Directors of the Castle-Trethewey deny that any immediate reorganization of the company is contemplated. The company still has $25,000 cash on hand, and if funds are needed for the building of a mill they will probably be borrowed. Above the 400-foot level there are 800,000 ounces in sight, and the mill ore is stated to average about 40 ounces to the ton. A crosscut will shortly be driven on the 550-foot level and if the results are equal to those in the upper levels the ore reserves should be doubled in a short time.

South Lorrain. — Canadian Lorrain Silver Mines, which has taken over the Maidens property in South Lorrain, has purchased a mining plant. The company is controlled by interests associated with the Keeley, and the property will be developed energetically.

The McKinley-Darragh has taken an option on the Paul claims in Lorrain, on which a silver discovery was made a short time ago.

The Mining Corporation has encountered silver at a depth of 50 feet in the new shaft being sunk on the Trout Lake property in Lorrain.

Porcupine.—Figures for the McIntyre year are not yet available, but it is understood that, notwithstanding the serious power shortage extending over approximately five months, the results will show an increase over the preceding year. One of the directors recently stated that no increase in the dividend rate would be made until the cash surplus has been built up. The company is considering the sinking of a central shaft to 5,000 feet, which will call for a large expenditure. Production at present is at the rate of approximately $300,000 a month, and with plenty of water in storage above the power plants, there is no reason why this rate cannot be maintained until next winter.

During the month of June, Dome Mines produced $421,799, as compared with $350,000 for the corresponding month of 1922 and $355,000 for May of the present year. This is probably the largest month's production in the history of the company, and it is understood that production will be maintained in the neighborhood of $400,000 a month.

Underground developments at the Vipond continue to be very promising and the company is making arrangements to increase its milling production to 180 tons a day. It is expected that this work should be completed by December, and in order to provide against an anticipated power shortage next winter, it is proposed to install a 300 h.p. Diesel engine in the mill. When milling is started it is expected that the grade of the ore will run around $10.00 a ton. On account of the insufficiency of power very little work has been done so far on the recent discovery on the 1,000-foot level, but preparations are being made to start several drills on this new vein.

A small 10-stamp mill at the Davidson was destroyed recently by fire. The loss, however, was very small, as the plant was not in operation.

Following the strike vote held a short time ago in Porcupine camp, an application has been made to the Dominion Department of Labor for a Board of Con-

ciliation to deal with the miners' demand for an increase of 20 cents a hour. Mr. Balmer Neilly will represent the operators, while Mr. Ryan will represent the men.. These two gentlemen have not been able to agree upon a chairman, so that this appointment will be left to the Government. It is expected that the Board will sit in Porcupine some time during the week commencing July 22nd.

NORTHWESTERN ONTARIO

Mr. Keefer's New Office to be in Port Arthur — The mineral, timber, agricultural, game and fisheries, and highway development interests of Northwestern Ontario, comprising that part of the Province lying between White River, 250 miles east of Port Arthur, and the Manitoba boundary 330 miles west of this city, are of such magnitude and growing importance, that administration from the seat of the Legislature at Toronto has been found to be not only time-wasting and expensive, but has been a distinct handicap on development, for the reason that the necessary attention their importance warranted could not be given them by Ministers of Departments under whose care they were. This condition caused the expenditure of large sums of money, and a great waste of time annually, by residents of this section in being compelled to visit Toronto, to lay properly before the Administration the needs and requirements of the various cases involved.

In order to overcome this difficulty, the newly elected Conservative Government has created a new office, that of Parliamentary Under-Secretary of the Departments of Mines and Lands and Forests, and have appointed Mr. Frank H. Keefer, K.C., M.P.P. for Port Arthur, to the Secretaryship. Mr. Keefer will open an office at Port Arthur and devote his whole time to the duties, with the necessary staff to take care of local legislative requirements, where anyone having business with any Department of Government may have it transacted without going to Toronto or communicating directly with the Government.

Mr. Keefer had his first case today, when strong representations were made by a deputation on a matter directly related to mineral development, which, without this office, would have necessitated a trip to Toronto, with added expense and delay.

Mr. Keefer is eminently fitted by a long residence and association with the needs of the western mineral interests, in which he has taken an intelligent and sympathetic interest. He is a firm believer in their possibilities.

NOVA SCOTIA

Charter Revoked. — The Communist leaders of District 26, U. M. W. A., have succeeded at last in defeating their own purpose. John L. Lewis, President of the U. M. W. A., has revoked the charter of the district as a means of disbanding its executive, and has appointed Silby Barrett, former International Board Member, as provisional President of the District, with authority to appoint a provisional executive and then hold an election. Thus the fiery J. B. McLachlan, in his defiance of the provincial and federal authorities, as well as of the U. M. W. A. headquarters, has succeeded only in bringing his dupes, the miners, into further disrepute in the eyes of the world, and in wrecking the plans of himself and his brother Communists for "Red" rule in Canada. The "mad adventure", as President Lewis termed it in his letter to Dan Livingston notifying him that his executive had been deposed, has served a useful turn in ridding the district of the domination of these misguided enthusiasts.

Unwise Leadership. — District No. 26 is now isolated, its charter revoked, and it stands without moral or financial support. It has not even the consolation of knowing that it had behind it a good cause. No intelligent workman, not even those on strike, can give a sound reason for the strike. They admit they are on strike for no concession in wages, no principle of agreement, no complaint against the Coal Company,— nothing but the removal of the forces which stand for law enforcement. They have been led into this plight of humiliating helplessness by leaders whose ambitions are irreconcilable with society as at present constituted, and like all honorable men they dislike to break away from their comrades. But many are breaking away, and many others have never joined the struggle. These latter saw the utter uselessness of it all from the beginning. Never did labor leaders play into the hands of their opponents and throw away every chance of winning as did these foolish men. Not again for a long time will the miners of Nova Scotia be able to win back the prestige now lost. Probably it is better that it should be so, for the land will have rest, — something very much needed.

Clear-cut Policy Required for Company. — It should not be forgotten, however, that much of the present agitation has developed through the weak policy of the British Empire Steel Corporation and through Federal Government meddling. Again and again the Company has receded and given way just at the moment they should have stood fast. They have had weak men at the helm of the Directorate who have been repeatedly taunted in the public press by the labor leaders for "crawling". This is a most humiliating light to be placed in before their employees and the public. The officials and office staff who had on all occasions loyally stood by their directors and who have helped greatly in the present crisis began to feel that such wobbling tactics could not be continued without loss of dignity, self-respect and a weakening of authority and discipline after each contest was over. One official, reporting his experience, stated that for several years he seemed to have done nothing but turn corners. Now if this large Corporation is to become a success it must have a firm and a clear-cut policy on which it can stand, and when labor disputes arise, each case must be settled on its merits. Too much temporizing and retreating destroys the morale and gives a false impression to workmen of their own strength, encouraging them to flourish the "big stick," as in the present instance.

President Lewis has played his part well, and though in the future there may be times when it might appear he is pressing a hard bargain, there can be no discounting his stand at this time when he has placed honor first and asked the members of his organization to return to work and stand by their agreement. Up to the present all the mainland lodges are with President Lewis, some in Cape Breton have swung into line and while for some time the extreme "Reds" may stand at bay, it may not be the worst that could possibly happen. All's well that ends well.

The Steel Strike.—The strike at the steel plant drags on, but each day sees an addition to the numbers of men at work. From 600 employees who remained on the plant, the number has risen to 1,800, and more

would be employed if the Company were able to put all the departments into operation. There never was any chance of the strikers winning out, and while the leaders tried to minimize in reports the number of men working, it is now beginning to dawn on even the dullest of the strikers that the cause is lost. The leaders still talk wildly of a 100 per cent. strike, and have never given up hope, while each day more men walk into the plant and begin work. Many new men are being hired on, and if the strike continues much longer, not a few steel workers may find that their places are filled and there is no work for them.

The efforts of Premier Armstrong and the Rev. Clarence McKinnon, who went to Sydney to try to negotiate a settlement of the dispute, failed. One thing they did suggest, however, before they left, and that was that a Committee of the striking workmen should be permitted to go to the plant and see for themselves the number of men at work. To this the leaders would not agree, for if they had agreed there would have been a sudden collapse of the strike, when the truth was known.

The coke ovens, the four open-hearths, one blast-furnace, the billet and blooming mills, are all in operation, the last mill working double shift. When the Company are assured of a continuous supply of coal all departments of the plant will be put into operation. The successful operation of the mills, in addition to the loading of coal from the stock piles, and to keeping some of the mines unwatered, has opened the eyes of strikers through the plant to the fact that they are not all-powerful.

BRITISH COLUMBIA

Premier Dividend. — The distribution on the Pacific Coast of the second quarterly dividend of the year to shareholders was commenced by the Premier Gold Mining Co., during the second week of July. It is said it amounted to 8 cents a share on 5,000,000 shares.

Dr. Camsell Discusses B. C. Minerals. — Dr. Charles Camsell, Deputy Minister of Mines for the Dominion, is inspecting mining conditions in British Columbia. His department, he states, is desirous of seeing prospectors direct special attention to mineralized districts adjacent to railways. The tendency is to go too far afield, with the result that nothing but the richest deposits found can be developed. "In the vicinity of the Canadian National, Grand Trunk Pacific and C. P. R. lines in British Columbia there is much ground that could be examined by prospectors, he says. "Being close to transportation, bodies of lower grade ore could be worked profitably whereas at greater distance they would have no present value."

There are seven parties, Dr. Camsell said, operating under the Canadian Geological Survey in British Columbia and the Yukon and, in addition, two topographical surveys are being conducted, one in the Kootenay Park District and the other in the Babine Range section. Dr. Harlan I. Smith, archaeologist and anthropologist, is employed in an examination of the botany and archaeology of the Bella Coola District and Prof. Jenness, who accompanied Stefansson on his Arctic explorations, is in the Hazelton District recording the customs, history, art, language and folk-lore of the Carrier Indians. Another geological party is making an examination of the bentonite deposits of the Provinces of Alberta and British Columbia.

Dr. Camsell visited Victoria while on the Pacific Coast and conferred with Hon. Wm. Sloan, Minister of Mines for the Province, on questions relative to British Columbia's interest, from a mining viewpoint, in the Imperial Economic Conference to be held later on this year in London. Hon. Charles Stewart, Federal Minister of Mines, and Dr. Camsell both plan attending this Conference.

Mr. Albu Discusses Canadian Mines and French Policy. — Leopold Albu, managing director of the General Mining and Finance Corporation of London, England, passed through Vancouver recently en route to Northern British Columbia and Alaskan mining fields. After personally inspecting some mining properties he will return East via California. In traveling westward Mr. Albu examined some of the larger mines of Northern Ontario. His company has extensive mining interests in South Africa, and in speaking of his impressions of this country he said that Canada has all the advantages of South Africa plus the priceless boon of ample water and profuse vegetation.

Capital for the development of mines and other enterprises has become "tight" in London owing to the uneasy feeling prevailing in England because of the turn of affairs in continental Europe, Mr. Albu states. This condition was likely to continue until business men obtained a more definite idea of how matters are going to be adjusted. He speaks very strongly regarding the policy of France stating that "France apparently has embarked on a policy more thoroughly imperialistic than that of the Napoleonic era. To business men her actions seem strangely out of tune with the times and her policy is undoubtedly having a very adverse effect on the post-war recovery of England."

The Outlook of Granby. — Col. J. T. Crabbs, of New York, president of the Granby Consolidated Mining & Smelting Co., after spending five weeks in British Columbia making a personal inspection of the company's plants and properties, and looking into local mining conditions generally, states that he has met with more optimism and a healthier spirit among mining and other business men than he did two years ago. From this he was inclined to think that prosperity was returning. As in the past, the Granby Company was prepared to do everything possible to assist. With the new properties in operation at Allenby the Company would have an annual payroll disbursement of $3,000,000, divided between Anyox, Cassidy and the new plant. Since the Armistice the payroll disbursements had been more than $10,000,000. In addition, capital expenditures of between $4,000,000 and $5,000,000 had been made, much of which had gone into the purchase of local equipment and construction materials. The railway right-of-way from Allenby to Copper Mountain had been damaged by landslides and it was expected that as soon as repairs were effected the new plant would be put in operation. With this mine and plant producing, the Company's annual copper production would total more than 50,000,000 pounds, the greatest single producer of copper in Canada. The company's properties were in good condition, ready to take the fullest advantage of any improvement in the copper market, and the possibilities of such improvement depended largely upon the settlement of the reparations problem in Europe. Four lean years had been bridged. During this period the company had operated at a loss, largely in order that its organization might be kept intact; but better times

were in sight and British Columbia's resources assured her, and those interested in her development, a generous share of the prosperity of the future.

Trail Ore Receipts. — During the first week of the month of July 9,756 tons of ore were shipped to the Trail smelter, Consolidated Mining & Smelting Co. The shipments in detail follow:

	Tons
Alamo, Alamo	47
Bell, Beaverdell	43
Bosun, Silverton	35
Company Mines	9,103
Granite, Taghum	3
Hercules, Burke, Ida	111
Knob Hill, Republic Wn.	54
Monitor, Three Forks	15
Mountain Chief, New Denver	28
Quilp, Republic Wn.	54
Ruth, Sandon	43
Silversmith, Sandon	173
Van Roi, Silverton	47
	9,756

First B. C. Silver Mine Re-opened. — The Eureka-Victoria, a silver bearing property situated near Hope, is being re-opened by A. S. Williamson and associates. This is the first metalliferous mine of which there is record in British Columbia. More than half a century ago it was closed down after operating successfully for some years. A tunnel was driven in the mountain side by the old timers on a rich silver vein and ore carrying high values was extracted. It was "mule-packed" down the Fraser River, shipped to Victoria, thence to San Francisco and finally to England. When the returns were received, amounting, it is said, to several hundreds of thousands of dollars, one of the owners went to Victoria to celebrate and never returned. The owners continued work for a time, but disagreements arose and the workings were deserted. Mr. Williamson states that the equipment has been found just as it was left, bunkhouse, cookhouse, rusted picks, shovels and drills and a dump of ore, not rich enough to pay for handling in the old days, but of value today. The tunnel timbers have rotted, of course, but with their renewal it will be possible to proceed with work where it was left off by the miners of the last century.

Fires at Anyox. — Some alarm was caused in mining circles recently by reports that a large fire was raging at Anyox, headquarters of the Granby Consolidated Mining & Smelting Co. Late information, however, indicates that, although the town and plant have been threatened by bush fires of considerable extent, the flames are under control. It is gathered that there has been some slight interference with the Company's operations but that a timely heavy rain came to the aid of the fire fighters before the condition became serious.

Exploration of Sultana Group. H. S. Munroe, general manager of the Granby Consolidated Mining & Smelting Co.; J. A. Bancroft, geologist; and E. J. Conway, mining engineer, have returned to the Coast after making an examination of the Sultana Group, which was bonded by the company some two or three months ago. There are showings of grey copper and silver bearing ore and exploratory work is to be undertaken immediately.

Silversmith Report. — The annual report of the Silversmith Mines Ltd., Sandon, just issued, is very interesting. It covers the period June 1, 1922 to May 1, 1923, and shows a cash balance of $94,337.15; government bonds on hand totalling $50,000; ore in transit $25,031.05 and ore on hand, $20,631.10. The gain for the year is said to have been $254,366.59. Dividends paid totalled $125,000 and there is $85,601 in surplus account. John B. White, president, in his report, states that the new mill and other improvements have been completed and that there should be no further capital outlay that will interfere with the payment of dividends. Operations include 52 feet of cross-cutting, 894 feet of drifting and 147 feet of raising. Clean ore, mined from stoping, totalled 522 tons and mill feed ore mined 34,843 tons. The average assay of the mill feed had been 24.02 ounces silver, 8.92 per cent. lead and 7.60 per cent. zinc. A 200 h.p. Diesel engine has been added to the power equipment as an auxiliary for use when the water is low in the winter.

Cork Province. — Drifting is in progress on the new ore-body struck in the Cork Province Mine, and the mill is to be operated 16 hours a day. Two carloads of concentrate have been produced, containing about 60 per cent. lead and 40 to 45 ounces of silver to the ton.

Yukon's Silver Output to Increase. — Captain George Black, M.P., discussing mining conditions in the Yukon Territory, which district he represents in the Dominion House of Commons, said that the placer industry was practically worked out but that silver mining was in its infancy. Two big mining companies already had invested heavily and other capital was going in this year, to his certain knowledge. Transportation companies, which handled 9,000 tons from Mayo this spring, were preparing to handle 25,000 tons next year. The government was putting in wireless stations at Mayo and Dawson and building roads to the mines. The White Pass & Yukon Railway was investing largely in the work of damming up the lakes that feed the Yukon River in order that water may be so released as to maintain an even flow for navigation.

Coal Production for June Up.—The coal production of British Columbia for the month of June totalled 186,160 tons, an increase of 23,848 tons over the output for the previous month. The collieries of Vancouver Island produced 129,616 tons last month which is 32,252 tons in excess of that for May. It is clear, therefore, that the coal business has been improving on the Coast and falling off in the interior. Greater mercantile activity, it is said, accounts for the growing strength of the coal market on the Coast. This should be felt most when the shipment of wheat via the Panama Canal begins, because there are few of the ships handling grain that are equipped for the consumption of oil. At any rate the present prospect, as far as the Island collieries is concerned, is encouraging. If the demand holds during the summer many operating difficulties will solve themselves automatically.

The Nicola Princeton Field, also, shows a slight increase in production, one thousand odd tons, for which the Middlesboro and Coalmont Collieries are largely responsible. In the Crow's Nest Pass Field there was a drop of 9,507 tons in the production for June as compared with May. The Coal Creek Colliery fell off 8,694 tons, that at Corbin 954 tons while the Michel Colliery increased its output 141 tons. The poorer showing in this section of British Columbia no doubt is accounted for by the barrier created by the Fernie

Tariff, making export to the United States at a profit practically out of the question, and the lack of demand in the middle west.

Competition at Blairmore. — A Mine Rescue Competition was held at Blairmore, Alberta, on July 2nd and 3rd under the joint auspices of the Mines Department of the Province of Alberta and the Rocky Mountain Branch of the Canadian Mining Institute. In addition to the Mine Rescue and First Aid contests for men, there were prizes for the best First Aid demonstrations by ladies (individually, and in teams) and a shield for Juvenile Competitors. In the Mine Rescue Competition there were eight teams from Alberta while British Columbia was represented by four teams, viz., Coal Creek; Fernie No. 1; Fernie No. 2; and Michel. Each team was given a different problem of a practical nature, such as may easily occur in a coal mine, involving the use of a breathing apparatus and a knowledge of First Aid and the work of the various teams clearly demonstrated the value of constant training with the apparatus in conjunction with organized team work.

The work of the competing teams was appraised as follows:

1st Place — Michel Team, B.C., and Hy Grade (Draw).
3rd Place — Fernie No. 2 Team.
4th Place — Bellevue No. 3 Team.
5th Place — Nordegg Team.
6th Place — Fernie No. 1 Team and Coal Creek Team (Draw.)
7th Place — A. B. C. Team Drumheller.
9th Place — Bellevue No. 1 Team.
10th Place — Blairmore No. 1 Team.
11th Place — Blairmore No. 2 Team.
12th Place — Lethbridge Team.

Much interest was shown in this competition as Blairmore is the main town of the Crow's Nest Pass District of Alberta.

The judges in this competition were: Messrs. Horne McDonald, Howell, and Cranston, Inspectors of Mines, Alberta, and Messrs. H. E. Miard and James Dickson, Mines Department, B. C.

The showing of the Fernie and Michel teams in taking two prizes in the first three indicates that a high standard of efficiency is being maintained in the use of Rescue Apparatus in British Columbia.

Poland has the largest known deposits of ozokerite, or mineral wax, in Europe. Last year the output was 430 tons, against 260 tons for 1921, this constituting the bulk of the world's supply. It is used locally to mix with lighter paraffin waxes in the manufacture of candles. Most of it is used as an electrical insulator in admixture with india-rubber. It occurs in veins, somewhat like the albertite of New Brunswick.

Ontario's Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

Hon. H. MILLS, Minister of Mines

Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth $48,128,387,of which the metallic production was $27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

Year.	Value.	Year.	Value.
1891	$4,705,672	1906	$22,388,383
1896	5,235,003	1911	41,976,797
1901	11,881,086	1916	65,308,822

Dividends.

Dividends and bonuses paid to the end of 1921 amounted to $23,140,734 for gold mining companies, and $84,388,185 for silver mining companies or a total of $107,528,919.

Mining Regulations.

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Publications.

All Shoulders To The Wheel!

So much interest and close co-operation has already been evidenced that the success of

AMERICA'S MOST IMPORTANT INDUSTRIAL EXPOSITION

is assured, and there is every indication that this year's Exposition will be the greatest of its kind in the country, if not in the world.

9th NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES

GRAND CENTRAL PALACE, NEW YORK

SEPTEMBER 17th-22nd

(The Only Chemical Exposition To Be Held This Year)

Everyone who knows what a tremendous factor chemical knowledge is to every industry "owes some of his time" to directing the attention of executives to the great benefits to be anticipated by a visit to this Exposition. There is no industry in the country that cannot be helped by the ideas to be given at this Exposition.

One of the important features will be the presentation of ways and means to enhance labor productivity. The utilization of waste products will also be given special attention.

Exhibitors are making elaborate plans to have this year's exhibit surpass any showing made during previous years.

For further information address National Exposition of Chemical Industries, Grand Central Palace, New York.

The Mineral Province of Western Canada

Has produced Minerals valued as follows Placer Gold, $76,542,203; Lode Gold, $109,647,661; Silver, $59,814,266; Lead, $51,810,891; Copper, $170,723,242; Zinc, $24,625,839; Coal and Coke, $238,289,565; Building Stone, Brick Cement, etc., $36,605,942; Miscellaneous Minerals, $1,358,839; Making its mineral production to the end of 1922 show an

Aggregate Value of $734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive $94,547,241; for five years, 1896-1900, $57,605,967; for five years, 1901-1905, $76,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for 5 years 1915-1920, $189,922,725; 1921, $28,066,641; for the year 1922, $35,158,843.

Production During last ten years, $339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing

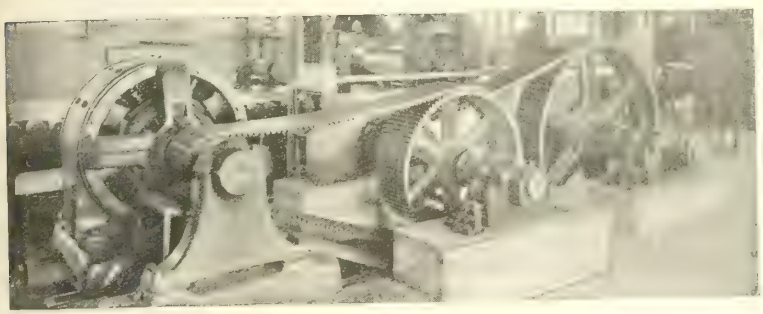
THE HON. THE MINISTER OF MINES,

MORSE CHAINS



A few of the Morse chains in use at the Raymond Lead plant

Using chain drives speeds up production, cuts belt expense and overtime wages and operates with practically no repairs.

Write for Booklet

CANADIAN AGENTS

Jones & Glassco, Regd.

MONTREAL, TORONTO.

O. W. Ludwig, *Plant Superintendent of the Raymond Lead Co., Chicago, says:*

"Thirteen years of service without a repair is our experience with two 100 H.P. and ten 20 H.P. Morse Silent Chain Drives.

"When we moved into our present plant thirteen years ago, we installed the present Morse equipment of silent chains for our two lead mills and ten hydraulic pumps. We had always previously used leather belts, but not without considerable trouble. For instance, if the operator was not careful — and gave the motors too great a load, the leather belt would slip and in some cases burn out. While with the Morse Chain Drive we overload them at times up to 15 H.P. without the slightest trouble.

"When we used leather belts on the hydraulic pumps, if a pump packing suddenly gave way, the water would squirt all over the pump as well as adjoining pumps, causing the leather belts to get wet. This often necessitated a shut-down on 3 to 4 pumps to dry out each belt, thus causing a loss of time by the men, which resulted many times in paying overtime to catch up on the work. Of course, with our Morse Chain Drive we have no such trouble—this positive drive prevents slippage and is not affected by water.

"Leather belts lasted us 2 to 3 years at the most, while our Morse Chain Drives have already lasted 3 to 4 times that long and seem good for many more years. So Morse Drives have cut our expense materially, speeded up production, cut out overtime wages and saved floor space, for they operate on shorter centers."

EXPERT TANK BUILDERS

for 35 Years

Each "Toronto" Tank is built with the purpose for which it is intended definitely before us. In design, material and construction it follows specified plans which our many years of Tank building experience have shown to be the most satisfactory for its particular type. **Specially** constructed for each industrial need — it is only natural that "Toronto" Tanks should give splendid service over long periods of time. We can supply "Toronto" (Mining) Tanks in B. C. Fir, Redwood, Gulf Red Cypress or White Pine — in any size or shape you desire. Estimates and specifications on tanks of special design, without obligation. Tank booklet free on request.

Small Compressors for Development Work

IT IS ESSENTIAL that a small compressor for development work be efficient, reliable and as nearly automatic in action as modern design and skilled workmanship can make it.

Efficient because the lower the cost of compressing air, the greater saving at the time when money is most badly needed and hardest to get.

Reliable because the property is more often than not isolated and if the compressor breaks down, work will be held up until repairs can be completed.

Automatic because labor is scarce and costly and the operator's time can often be used to better advantage in other ways.

For this class of work there is no simpler or better combination than an Ingersoll-Rand Class ER, or FR Compressor and Ingersoll-Rand "Jackhamers" or Convertible Drifters and Sinkers.

You can always satisfy yourself as to the value of this combination before buying as it is easy to locate nearby installations where the worth of such plants is being constantly proven.

Class ER and FR Compressors are straight-line, single-stage, double-acting units fitted with Ingersoll-Rand Plate Valves. They are simple, sturdy, compact in construction, reliable, automatic and economical in operation. Class ER units are furnished for a long or short belt drive; Class FR for Steam drive.

When operations have reached a stage warranting the purchase of a larger compressor, these units can be used as auxiliaries or readily sold at a price which will help materially in buying a larger machine.

Due in part to their long life and excellent reputation this has become the usual practice in many mining camps and our records show that some of our older machines have been used for opening up no less than five or six producing mines in succession.

A Bank That Is Always Near

The mining engineer — moving as he does from place to place — must needs utilize a bank which has branches conveniently located in mining centres.

The Imperial Bank, with 192 branches throughout Canada and with special concentration in mining districts, offers distinct advantages to those engaged in the mining industry. Patrons of this Bank are never far from their bank accounts, no matter to what part of the Dominion they may go.

Why not ensure adequate banking facilities by depositing your funds with this Bank?

ASSESSMENT WORK AND MINE TAXATION

The new Premier of Ontario already is showing an active interest in the province's mineral resources. The de-centralizing of the government offices to the extent of appointing Mr. F. H. Keefer as resident representative in Port Arthur is an experiment whose progress will be followed with interest by mining men. The three hundred mile stretch of mineral-bearing land from Nipigon to Kenora of which Port Arthur is the natural centre constitutes one of the chief potentially productive areas in Ontario. For a variety of reasons, its exploration has remained incomplete and attempts to develop it have been unsuccessful. It still remains a promising field for honest and well directed effort. We hope that Mr. Keefer may succeed in aiding this effort.

Mr. Ferguson has announced that his government is prepared to examine, and if necessary modify, the regulations in the Mining Act dealing with assessment work, with a view to stimulating the active development of mining claims. It is a debatable question whether an addition to the present annual requirement of assessment work would aid or retard exploration. Advisers of the late Government made the existing regulation in an honest attempt to effect the very end Mr. Ferguson desires. There is one point in connection with the assessment regulations, however, on which most real prospectors and mining men will agree, and which well warrants the Premier's attention. A vast amount of assessment work is sworn to in the recording offices that has not been performed. From our own experience we would judge that non-resident owners, particularly amateur prospectors and those that take a "flier" on a mining claim or two and hold them "on spec..," are those most often guilty of perjury in this connection. Genuine prospectors and mining men, upon whom depends almost entirely the progress of the mineral industry, usually do their assessment work before they swear to its performance. It is up to the provincial government and the public officials to see that all conform to the law.

Another point in the present mining regulations that might well engage the attention of Mr. Ferguson and his associates is an anomaly in the taxing of mines. During the hey-day of wartime prosperity the nickel mines were singled out for special taxation.. This we consider to be now an injustice, whether or not it was so at that time. The managements and directorates of the nickel companies have an enviable record of war service. They continued to produce and sell an essential war material at substantially the pre-war prices, and re-invested part of their profits in additional plant to provide the larger output required, with the full knowledge that it would be virtually useless after the war. They neither asked nor received the subsidy that induced many to contract similar obligations in other lines. The effort toward post-war rehabilitation of an industry cut off from the larger part of its former market has been remarkable, and admirable. We suggest that Mr. Ferguson examine into this case closely, and we recommend that justice, even though tardy justice, be done the nickel companies.

"FAR-AWAY FIELDS—"

Canada has vast unprospected areas. Few realize what a substantial percentage of these areas lie close to railways and navigable water routes. The search of the prospector is conducted ever outward and onward, to new fields and the unmapped wilderness. The spirit of adventure that stimulates the search on the outskirts should be encouraged by every possible means, that the boundaries of our settlements may be extended. But the near-by mineral areas should not be neglected.

Last week our British Columbia correspondent quoted Dr. Charles Camsell, Deputy Minister of Mines at Ottawa, as saying that his department wants to see prospectors direct special attention to mineralized districts adjacent to railways. The tendency is to go too far afield, with the result that only the richest deposits found can be developed. "In the vicinity of the Canadian National, Grand Trunk Pacific and Canadian Pacific lines in British Columbia there is much ground that should be examined by prospectors," said Dr. Camsell. "Being close to transportation, bodies of lower grade ore could be worked profitably, whereas at a greater distance they would have no present value."

This is a good tip to those prospectors with whom the desirability of making a profitable "find" outweighs the undoubted attractions of exploration far afield. There are numerous mineralized areas in Nova Scotia, Quebec, Ontario and British Columbia that are intersected by or close to railways that have had, in general, only the merest superficial examination. Most of them have been the scene of a "boom" that accom-

plished little or nothing in the way of exploration or mining development, but left a legacy of blasted hopes, distrust and discouragement. In some of these areas a large part of the ground formerly held as claims by private owners has reverted to the Crown for non-payment of taxes. Some of the properties still held by private owners can be obtained from them on reasonable terms. One can say, in general, that, unless they are known definitely to have been explored thoroughly, these old-time mineral areas are the best prospecting ground in Canada.

FEDERATION OF BRITISH INDUSTRIES AT EXHIBITION

The spirit of Empire development is in the air these days, and numerous means are being evolved to put it into material form. This month there will be exemplified, in Toronto, a very practical means of developing Empire trade. The Federation of British Industries will have important exhibits at the Canadian National Exhibition for the first time. The move is somewhat in the nature of an experiment, and if successful it is intended that the exhibits of succeeding years shall be increased in scope and magnitude. The exhibitors are, of course, almost exclusively manufacturers; but as these must have raw materials, many of them imported into Great Britain, to conduct their business, Canadian producers of raw materials, including minerals and metals, may find in the Exhibition of 1923 a convenient and useful means of enlarging their British connection.

The sudden rise of the Federation of British Industries is one of the romances of British commerce. It was founded in 1916 by a small group of prominent manufacturers who realized the necessity for some organization to coördinate the interests of, and represent, all the industries of the United Kingdom. The original idea of its founders was to enable manufacturers in the United Kingdom to take immediate advantage of commercial opportunities overseas, following the conclusion of the great war.

Once begun, the Federation grew so rapidly that at present it is the largest and most powerful organization of manufacturers and raw material producers in the world. Its membership includes all the important trade associations in the United Kingdom, over 120 in number, while altogether its total direct and indirect membership includes more than 19,000 manufacturing establishments, representing $25,000,000,000 in capital. In addition to its head office in London, it maintains sixteen district offices, each in charge of a resident secretary, in the principal industrial cities of Great Britain and Ireland.

In this initial appearance at the National Exhibition in Toronto, twenty British firms have arranged for large exhibits and thirty more will show their goods on a smaller scale. A number of these exhibits will be of direct interest to mining men — for example, steel, mining machinery, firebrick and scientific instruments. More important, however, will be the opportunity presented for personal contact with the responsible representatives of the British firms. Britons and Canadians have common interests that are bound to be forwarded by personal acquaintance gained in such a way as this.

We hope that this attempt to aid the development of Empire trade will be so fruitful of practical results as to encourage an annual British exhibit of increasing size and importance at our Canadian National Exhibition.

STATE PROSPECTING

State-aided enterprises are more the vogue in Australia than in any other part of the British Empire. A new departure, recently described in the report for last year of the Western Australia mines department, is prospecting by public officials. The gold industry of Western Australia has declined so seriously that this expedient has been adopted in an attempt to revive it. A party of nine men qualified to conduct a search for minerals was kept in the field last year, and the result was so encouraging that the State government has repeated the experiment again this year. The idea is virtually that the work of these public servants will provide sufficient information to stimulate a "rush" of prospectors and miners.

In Canada we have developed virtually this same expedient, though we call it by a different name. Our provincial and federal Departments of Mines have the prospector and his work continually in mind. The Geological Survey, particularly, has laid itself out to direct the energies of the prospector. As the preliminary areal mapping of the country is now to a large extent finished within economic distances of the railways and navigable water routes, the attention of the geologists is being directed more and more to the areas likely to be productive of mineral wealth. These are mapped in more detail and their geological problems studied and solved, and in every report on such an area made during recent years the prospector will find directions for his guidance that he can understand and follow.

The Ontario Department of Mines has likewise a close *liaison* with the prospectors. Its geologists, working principally in areas where an intensive search for mineral deposits is already in progress, come into close personal contact with the searchers, with a result that is mutually beneficial and that adds much to the efficiency of the prospector's effort.

Thus, though we have in Canada no state prospecting under that name, we have, in our geologists, a

corps of men working with good effect to aid and abet the search for minerals. Though they are only a handful, scattered from Atlantic to Pacific, their influence on the mineral industry is remarkable. Working cautiously, steadily and with the full force of scientific knowledge behind them, this little band of public servants accomplishes a result each year quite out of proportion to their numbers, and more nearly in accord with the zeal for progress and the thirst for still further scientific knowledge that is their outstanding characteristic.

SEVEN DOLLAR RATE ON ALBERTA COAL

Little publicity has been given the conference in Edmonton last month, between representatives of the railways and coal operators, under the auspices of the Government of Alberta. Their object has been to "get together" with a view to determining the minimum rate at which it is possible to haul Alberta coal to Ontario. Apparently the conference has been at least partially successful. A press despatch from Edmonton states that on July 26th fifty cars of Drumheller coal was shipped over the Canadian National lines to Ontario "under the new agreement between the Government and the railway authorities, the coal going forward at the temporary freight rate of $7.00 per ton."

This is good news. Evidently the railway men have conceded the fact that their former announcement of a $9.00 freight rate is susceptible of revision, and that under the circumstances it is worth while to determine by actual trial the cost of shipping the coal in trainload lots. The season is now so far advanced that these experimental shipments can be sent forward during only the few short weeks that remain before the wheat crop commences to move eastward; but it is highly satisfactory to know that, following the manoeuvering that has been in progress since last spring, those concerned have agreed upon a basis for action.

After these experimental shipments have been made, it will still remain to determine whether or not it is economically feasible to reduce the cost of hauling by the use of specially designed rolling stock. It seems possible that in the case of coal, which can, if necessary, be shipped steadily throughout the twelve months of the year, such special equipment might be justified. The data accumulated as a result of the shipments already arranged for will, we hope, point the way to further progress in the direction of independence in fuel needs.

AIRPLANE AIDS SURVEYS

The Geological Survey has been conducting an important experiment in conjunction with the Air Board since last year. The use of aerial transportation and aerial observation in helping to solve the field geologist's problem is receiving a thorough trial. Last year supplies were to have been taken in to a topographical survey party in a far distant part of Northern Manitoba. The attempt was only partially successful; but no serious consequences ensued. This year the attempt has been renewed, with more success. Dr. J. T. Wright, who is in charge of the survey party in the Rice Lake gold and copper-nickel area east of Lake Winnipeg, has received a shipment of supplies from Victoria Beach, the flying base on Lake Winnipeg. Mr. R. C. McDonald, who is making a control survey of part of the vast unmapped area north of The Pas, will have received supplies by airplane by this time. It has been planned also to take the geologists up in the air, to observe the topographical features of the ground they must cover on foot and by canoe, and also to provide them with oblique photographs of the area. This direct observation, supplemented by sketches, in conjunction with the photographs, which cover a wide area when the view is oblique, will aid the surveyers very materially; while the supplies, brought hundreds of miles in a day, will save weeks of work on the portage routes.

This is a very important development in the surveying of our unknown hinterlands. The time and expense involved in the present methods of mapping impede its progress. The mapping is the first step in exploration and commercial exploitation. If the use of the airplane will hasten and cheapen the surveying of our northland, we shall benefit the more rapidly from the natural resources it contains.

THE ENGLISHMAN

Then and Now

Time was when, weirdly clothed and garbed,
He roused our caustic comments, barbed
With adjectives unkindly.
Equipped with bath-tub and with guns,
He was the type of Albion's sons
Who went it blindly.
His speech was strange, his manners bad;
He was an unengaging lad,
For work unfitted.
Lo! Time a miracle has wrought:
The Englishman has taken thought,
Has pretermitted
His lofty, irritating mien,
And (stranger thing has never been!)
Will, as a sequel,
Some day, that has not dawned as yet,
Treat us Canadians, I bet,
As quite his equal!

J. C. M.

Plans to Make Gold-Wealth of Ontario Known to the World

Interview with the Hon. Howard Ferguson, who intends practical steps shall be taken to assist development of the gold-mining industry, accorded to Mr. Howard Bridgewater, Director, The Porcupine-Davidson Gold Mines

Mining men throughout this Province, and many in the Old Country, will be gratified to learn that it is the intention of Ontario's new Premier that active steps shall be taken to make known to the world — and particularly to the financiers and investors of Great Britain — the wonderful opportunities for the profitable investment of capital that awaits enterprise in connection with the development of Ontario's gold resources. American and English mining engineers who have visited the goldfields of Porcupine and Kirkland Lake, to say nothing of the other promising districts such as West Shining Tree, Matachewan, Lightning River, Matheson and Larder Lake are enthusiastically agreed that not only is Northern Ontario one of the richest known mineral areas of the world, but that its gold-fields bid fair in time to rival even the Rand, the greatest gold-field the world has known.

According to so eminent an authority as Mr. C. V. Corless, mining is Canada's greatest future industry, and her future greatness rests therefore more upon the extent to which her mineral resources are developed than upon any other factor. In his Presidential address to the Canadian Mining Institute (delivered in March of last year) Mr. Corless said: —

"We live in a country whose greatest permanent material sources of wealth are its soil and its minerals. Few people realize however that not more than 15% of its entire surface is suitable for profitable cultivation. ...I shall endeavour to show that the remaining 85% contains mineral treasures of inconceivable value."

No one will gainsay the fact that the greatest need for capital in Ontario exists in connection with the further development of the gold-mining industry. Not only can we point to a mine in the Province field, the Hollinger, which is the greatest individual gold-producer in the world, and to others that may quite possibly rival it in importance, but we can point to the fact that of the many mines in the development stage, results have in numerous cases justified deep working, both in the Porcupine and Kirkland Lake fields. And we can point further to the fact that the geological structures favourable to the formation of workable deposits have been proved by Government geologists to extend for a distance of upwards of 100 miles across the border into Quebec.

Conditions are probably more favourable to mining operations here than they are in any other quarter of the globe, working costs comparing favourably even with those of the old-established Rand mines, despite the advantage the Transvaal has in its supply of cheap "native" labour.

Asked to express his views on this subject, Mr. Ferguson said: — "You may tell your readers that the new Government, over which I have the honour to preside, is fully alive to the importance of vigorously developing the mineral, and in particular, the gold-wealth of Ontario. The main need of our gold fields is capital for their development. We undoubtedly have the mineral wealth and it is the intention of the Government to let the world know. Up to now private enterprise has had little assistance from Government, little or no attention having been paid to representations from London mining houses concerning the need to familiarise the British investor with the present and prospective gold-wealth of the Province. Amongst the many and various proposals that are receiving consideration is one to invite representatives of the leading British newspapers to visit the gold fields of Ontario as guests of the Government so as to give them the opportunity of seeing for themselves not only what has been accomplished, despite many difficulties that no longer exist, but what yet remains to be done. This proposal is now receiving sympathetic consideration. The results of such a visit would, I am convinced, be so important as to render the expense incurred scarcely worth consideration.

"Of the other proposals that have been brought to my notice, I would prefer not to say more at present than that they will all receive the close and careful attention they merit. Conditions for gold-mining are nowhere more attractive than they are at present in Northern Ontario; it remains for us, therefore, to see that their attractions are made known. Our light will no longer be hid beneath an agricultural bushel!"

NEW PROCESS FOR MAKING ALUMINIUM

A patent has recently been taken out in Germany for a new method of manufacturing aluminium, whereby clay is mixed with pyrites and heated to about 500° C. On continuous calcination, in a stream of chlorine gas evolved from sodium chloride, with the addition of carbon, the resulting reaction-product decomposes into aluminium chloride, which is then mixed with sodium chloride, to which are added potassium chloride and small quantities of strontium chloride. Transformation into metallic aluminium and chlorine gas is then effected by the usual thermo-electrical means. No cryolite is used, nor is it necessary that the clay should have a fixed proportion of silicic acid present. Moreover, in this process the chlorine gas necessary to form the aluminium chloride is not wasted.

Another patent has been taken out to recover aluminium from laterite iron ores such as are found, for example, in Greece, containing relatively high percentages of aluminium. The latter, on the ore being smelted, passes into the slag and is lost. Under the new process, the ores are subjected to a reducing pre-treatment, such as heating the finely-ground ore under exclusion of the atmosphere to high temperatures in order to bring the colloidal oxides into a suitable form for reduction. When this has been effected, the actual reduction is done by passing reducing gases over the said oxides. Both heating to these high temperatures and reduction can be done simultaneously by passing a reducing gas, say water-gas, over the mass of ore. The reduced mass then contains the metallic iron in a state of fine division, and it can be removed by magnets, leaving the remainder to be worked up into aluminum. — "Aluminum"

The Collieries of British Columbia

IV. — Canadian Collieries (D), Cassidy, and Nanoose-Wellington

By ROBERT DUNN

The largest producer of coal in British Columbia is the Canadian Collieries (D) Ltd. Its output in 1921 was 736,480 tons. The Crow's Nest Pass Coal Co. Ltd. runs it a close second with 691,824 tons in the same year and, as has been noted, the Western Fuel Corporation is not far behind; but the Canadian Collieries holds the palm. This company has easily the greatest extent of coal lands on the Island. In June 1910 it acquired by purchase all the Dunsmuir interests. These interests comprised the coal of the lands of the Esquimalt & Nanaimo Ry. Belt that had not been alienated prior to the year 1884. In that year the Settlement Act was passed, which conveyed to the E. & N. Ry. Co., the chief promoter of which was the late Robert Dunsmuir, the block of land known as the E. & N. Belt, together with the under-surface rights, including coal and base metals. Some settlers subsequently were able to obtain the coal on lands within that area under the Settlers' Rights Act of the Province of British Columbia, their title being secured by reason of their showing that their holdings came to them direct from settlers who located before 1884. A few such grants were transferred by purchase to the Granby Consolidated Mining & Smelting Co., which explains the ownership of the Cassidy Collieries. Substantially, however, the Canadian Collieries (D) Ltd. hold the entire Dunsmuir coal rights on the Island and since entering into possession in 1910 large expenditures have been made in developing and improving the property.

Surface Plant at No. 4 Mine, Cumberland, B. C., Canadian Collieries (D) Ltd.

The Ladysmith Field

The Canadian Collieries' operations are divided into two distinct fields. The more southerly of these is Ladysmith. It consists of Nos. 1, 2, 3 and 5 Mines, the first three being located at Extension, about eleven miles from Ladysmith, and the last at South Wellington, a point on the E. & N. Ry. about nine miles north of Ladysmith. The product of the Extension Mines is carried to Ladysmith, the shipping centre, by means of a standard gauge railway, while the South Wellington coal is transported over the E. & N. Ry. There is a central tipple at Extension through which goes the coal of the three mines, which are connected by a main tunnel. Electric locomotives take care of the haulage and the pillar and stall system is used. The main washery is at Ladysmith, adjacent to the shipping piers, and facilities are maintained for both large ocean-going vessels and local business.

The Comox Field

In the second field at Comox, there are five mines, viz., No. 4 Slope, No. 5 Shaft, No. 6 shaft (not operating) No. 7 Slope (abandoned) and No. 4 Shaft (not operating). There has been constructed here one of of the largest and most modern hydro-electric plants in the Province. The power house is located on the Puntledge River about three miles from Cumberland. The generating units are as follows: two Francis R turbines direct connected to two Canadian General Electric generators with an installed capacity of 12,000 h.p., accommodation being available for an additional installation of 12,000 h.p. Power is carried to sub-stations located at each mine, as well as the shipping docks and the main shops at Union Bay. The towns of Courtenay and Cumberland secure power for lighting and other purposes from the company's plant. Several of the rural communities are similarly served. The mines are equipped with the latest type electrical hoisting equipment and, while longwall mining has been the practice where conditions seemed to warrant it, the pillar and stall system is that generally in use. The shipping point for Comox coal is Union Bay, at the head of Baynes Sound. At this point the Company have large shipping docks equipped with electrically-driven conveyors and other loading facilities. A modern washery and coal preparation plant is also located adjacent to the shipping docks. At Union Bay are the general shops consisting of machine, car, foundry, blacksmith, and carpenter shops. A standard gauge railway connects the mines and Union Bay, and it may here be noted that, although the mines are

only four miles from tidewater, the railway is some eighteen miles in length, having to adopt a circuitous route in order to obtain a good grade. The motive power consists of five steam locomotives ranging from 40 to 71 tons, 50-ton steel hopper cars being used for transporting coal. A regular passenger and freight service also is maintained, connection being made with both E. & N. Ry. Company trains and the Canadian Pacific Ry. boats. A battery of 200 beehive coke ovens is located at Union Bay.

Personnel of Canadian Collieries (D)

J. M. Savage is the general manager of the Canadian Collieries, with headquarters at Victoria. The general superintendent is Thos. Graham, while at the Wellington-Extension Colliery, Thomas A. Sprunston is the superintendent. At Comox the district superintendent is Charles Graham. The development of the coal areas under the company's control in a broad way, looking to the future and providing intelligently for present market requirements, has been the policy of the mangement in recent years. Mr. Graham, the general superintendent, besides being a practical operator with years of experience and intimate knowledge of the Island fields, was one of the first to take an interest in "Safety First" measures. As Chief Inspector of Mines he took a very active interest in this phase of underground work, and his concern for the safety of the men has been manifested in many ways since then. In recent years the Hon. Wm. Sloan, Minister of Mines, has introduced from time to time regulations under the "Coal Mines Regulation Act" for the protection of the lives of coal miners, and under Messrs. Savage and Graham this company always has promptly and unhesitatingly complied with the same.

Part of Surface Plant, Cassidy Colliery. Note slope in left foreground and manway in center foreground

Cassidy — an Ideal Colliery Village

The Granby Consolidated Mining & Smelting Company began the development of coal lands at Cassidy, a few miles south of Nanaimo, in 1917, chiefly with a view to supplying coal for their by-product coke ovens, then newly installed, at Anyox, one of the important copper smelting centres of British Columbia. No expense was spared in making Cassidy as ideal colliery community and in point of artistic finish, together with conveniences and entertainment facilities for the benefit of the men, it stands by itself in this Province. The streets are boulevarded, the houses surrounded by lawns and flower gardens, modern sewerage and waterworks systems are provided; there has been laid out one of the finest athletic parks in the country, with baseball diamond, football ground, tennis courts, bowling green and quarter-mile track; a natural grandstand is furnished by the hillside back of the field which the Company has reserved, together with the timber, as a natural park; and there is a recreation hall containing a variety of modern amusement equipment. The houses are varied as to architecture and the rooming house, containing about eighty rooms, is steam heated, electric lighted and each room has running hot and cold water. Furniture and bedding are supplied. The entrance to the mess house is through a pretty, vine-covered pergola, while the dining room, which is steam heated in winter, contains small tables each seating six men. The kitchen is equipped with electric dish washing machine, vegetable paring machine, tables heated by steam coils to keep dishes hot, and a large bake oven and refrigerator plant. There are also a first-class change house; a hospital and a First Aid Station equipped with Gibbs apparatus, smoke chamber etc., as well as a lecture room for first aid and other instruction; and well fitted carpenter, machine and blacksmith shops. The tipple is up-to-date, the track scale being a Fairbanks standard, steel-and-concrete, and the rock cars are handled with special Wilson rotary dump. The washery, as at first installed, has two 2-compartment jigs with a capacity of 40 tons an hour each, together with a sludge recovery using the same water repeatedly. The washed slack is used at the Anyox by-product ovens, the lump, nut and some pea coal being sold. Subsequently there were added seven Deister-Overstrom coal washing tables for washing the fine slack and a Dorr thickener 75 feet in diameter. At first the power plant consisted of two Badenhauser water tube boilers, 260 h.p. each, fired by mechanical stokers, the ashes being removed by washing and fluming to the dump. Later the power plant capacity was increased by a 360 h.p. B. & W. boiler. The compressor is a Rand cross-compound condensing, capacity 2,000 cubic feet of free air a minute, which is used for supplying the underground drills, pumps and hoists. Electric power is supplied by an Allis Chalmers 450 kw. generator and an auxiliary unit, 250 k.w. The rest is of Westinghouse make. A Worthington fire pump, capacity 1,000 gallons a minute, is provided for emergency. An electric locomotive and six

automatic side-dumping cars of the Granby type were added to the surface equipment in 1921.

Cassidy Underground Development

The mine is opened on the full dip of the seam, the main slope being driven 7′ x 14′ in the clear to allow for double track, a separate manway being provided as a travelling road. The pillar and stall system is used, the panels being relatively small as a precaution against fire, and large pillars are left along the main haulage ways and permanent airways. As far as possible gravity is used in delivering coal from the working faces to the main haulage system, and storage battery locomotives are utilized on the underground levels. Ventilation is supplied by a Sirocco fan with a capacity of 150,000 cubic feet of air a minute, which is driven by a 150 h.p. Westinghouse electric motor. The fan house is of concrete,as are also the housings for the telephone exchange and the motor generator set for charging storage battery locomotives. The mine cars are of wood, with a capacity of 1¾ tons.

A problem has been presented to the colliery management in recent months in the form of more or less frequent outbursts of gas, the first one occurring on January 14th, 1921. The coal displaced by this means has run as high as 150 to 400 tons. As a rule these displacements are not violent, simply moving the face forward from ten to fifteen feet. Sometimes the coal is powdered and, as there has been no violence, it is assumed that it is in a fine state of division in the pocket in which the gas has been contained.. An analysis of this dust showed an ash content of 40 per cent. As a result of this condition the British Columbia Department of Mines has made some special rules. The use of powder underground has been prohibited and boring in advance of the working faces is being insisted upon.

C. M. Campbell, the superintendent of the Colliery, has assembled an efficient staff about him. Under his management the industry has advanced in the course of a few years to one of the most important of Vancouver Island in point of production. In 1921 its output was 268,962 tons.

Nanoose-Wellington Mine

The Nanoose-Wellington Collieries Co. Ltd., with a production in 1921 of 50,206 tons, is situated at Nanoose Bay, about nine miles north of Nanaimo. The mine is worked on what is known as the Old Wellington seam, which is reached by a shaft 8′ x 16′ at a depth of 133 feet. The seam varies in thickness but the coal is of excellent quality. Generally speaking the pillar and stall system is used, although longwall has been adopted on occasion. The plant consists of three boilers with a total h.p. of 360, two compressors delivering 950 cubic feet or free air a minute, and a first motion hoisting engine of 75 h.p. Electrical power is generated by a 150 k.w. generator, and the power is extensively used in the screening and washing plant. Haulage has been shortened by a new level and the main level has been relaid with 30-lb. steel rails, and some sharp curves removed. The storage bunkers have a capacity of 1,000 tons, coal being conveyed thence to the shipping point on the water front by means of cars. A conveyor belt has been installed at the company's wharf, immensely improving loading facilities. Although housing conveniences have been provided at the mine, a "jitney" service permits men to travel between Nanaimo and their work. The Wheat electric head-lamp is used and has been giving general satisfaction. J. A. Coleman, resident at Seattle, Wn., is the managing director and James W. Jemson, the mine manager.

Other Collieries

Several other collieries warrant brief mention. The Pacific Coast Coal Mines, Ltd., superintendent George Wilkinson, has not been operating since 1921 owing to financial complications which have involved prolonged litigation. Its chief property is the Morden Mine, which is situated in the Cranberry District about two miles from South Wellington, and is worked on the Douglas seam. The mine is entered by two shafts sunk to a depth of 600 feet, and ventilation is produced by a Sheldom double entry fan 7 feet in diameter, driven by a 16″ x 17″ Vulcan Iron Works engine. Within the past two or three years there has been a complete overhauling of the boilers, steam lines, electric units and screening plant, the railway has been regraded in part, and the Boat Harbour plant, (the shipping point) has been given necessary attention. The Jeffrey-Robinson washer has been practically rebuilt. The underground and surface equipment is in good shape and the mine is ready for resumption of work when financial and legal difficulties are removed. In 1920 the output of this colliery was 94,904 tons.

Messrs. King & Foster, headquarters Nanaimo, are taking a few thousand of tons a year from the old Adit Mine, on the original Wellington seam, which formerly was operated by R. Dunsmuir & Sons. Their operations are being extended so that the output is expected to grow steadily.

The East Wellington Coal Mines, Limited, are opening a mine adjacent to the old "Jingle Pot" area a short distance west of Nanaimo. It is on the Wellington seam and the company, which has acquired 750 acres of coal land, will use the plant and wharves of the abandoned "Jingle Pot" Mine. The seam is 5½ feet thick and is expected to yield, within the area indicated, 6,000,000 tons. H. W. Maynard is president and J. J. Grant, general manager of the company.

Present-day Conditions

Coal mining on Vancouver Island is not now the simple matter it was twenty or thirty years ago when R. Dunsmuir & Sons were making their fortunes and the chief export market was San Francisco, a point from which scores of thousands of tons were distributed annually at a good profit. No longer can the coal be taken almost from the grass roots and shipped at relatively small cost for production and freight. The old workings are far advanced, the haulage distances are much greater, and the market demands in point of quality much more exacting. On top of this the seams are badly faulted in places and it requires technical knowledge of a high class, as well as intimate acquaintance with local conditions, to keep consistently in the coal. The handling of larger quantities in much more extended underground workings has necessitated far closer attention to safety measures. It is to the credit of the operators, as well as to the watchful inspectors of the Department of Mines, that the industry has been carried on without more accidents than have happened. True, there have been disasters, but the close investigation that always follows usually has proven that the cause was some thoughtless disregard of known regulations. These unfortunate

experiences from time to time have brought to light conditions open to improvement, and where that has been shown the necessary rules invariably have been formulated by the Government and as invariably have been cheerfully adopted by the companies. First Aid and Mine Rescue Work engage the attention of men in all the mining centres, encouraged in practical ways both by the Government and the colliery managers. There are Government stations at Nanaimo and at Cumberland. The Gibbs Apparatus is used at the former centre and the Paul at the latter, and in both places the keenest interest is taken in all First Aid competitions. The best of good feeling exists at present between all those engaged in the industry on the Island. The industry never has been in more satisfactory circumstances, and the Island field, given the market, is capable of a much greater annual production than the average during the past five years.

LETTERS FROM READERS

That Decimal Point!

To the Editor, Canadian Mining Journal,
Sir,

In your issue of July 20th, p. 544, in the article on Natural Gas and Petroleum Resources of Western Canada, the following statement is made. "In the United States the production of carbon black is an important industry with an annual production of about fifty million pounds in the manufacture of which some forty-one million cubic feet of natural gas are consumed." I should think there were "some." That is more than a pound of carbon black is recovered per cubic foot of gas.

The weight of a cubic foot of natural gas with specific gravity of 0.6 is .045. Assuming the gas is all methane or CH_4 there would be 12 of carbon and 4 of hydrogen, or 75 per cent carbon in the gas. Multiplying the weight of a cubic foot of gas, viz., .045 lbs. by .75 gives about .03 lbs. as the total carbon in a cubic foot. Not more than one-tenth of this would be recovered in the form of carbon black. I take it the decimal point should be shifted over several places, if not, the manufacturers of carbon black are wasting their time in doing something trivial, they should be working on the problem of Perpetual Motion.

Explain to us, Editor, what you mean by allowing such statements to be set before the young and innocent.

"Reader on the Ninth Concession"

* * *

(We refer our "reader on the Ninth Concession" to the Mines Branch Summary Report for 1921, page 59, where R. T. Elworthy says: "In 1921 fifty-eight million pounds [of carbon black], valued at over $5,000,000, were obtained from 49,000,000,000 cubic feet of gas in the United States. The process is very inefficient, as only about 1 to 1.2 lbs. of black is produced from 1,000 cubic feet of gas, compared with a theoretical yield of about 40 (2.5 per cent recovery.) Although investigations have been carried out with a view to increasing the efficiency, thus far it has only been obtained by a corresponding sacrifice of quality in the product. Here is an opportunity for the physical chemist." The statement in our issue of July 20th should have read "some forty-one *billion* cubic feet of gas. We have not yet reached the point of efficiency indicated by Mr. Elworthy as so desirable." — Editor.

PROGRESS ON COLONIAL

Inquiry has disclosed the fact that Continental Mines, in running a crosscut on the Colonial at Cobalt from the contact orebody at the 940-foot level, has struck another vein. The company is said to be shipping 20 tons of milling ore daily from development. The higher grade ore is being stored in one of the old Colonial stopes. It is understood, as soon as 3,000 tons of ore have accumulated in the stopes, shipments will be made at the rate of 100 tons daily. A contract has been entered into with a local concentrator to treat the milling rock. No details are forthcoming as to the new Colonial orebody, other than that it "carries native silver and good mill-grade."

The first vein encountered on the Colonial is yielding milling ore, but laterally the exceptional width of nine feet and over was not maintained. Development work has indicated that the best values lie above the contact and that the vein will probably extend upwards for a distance of about 300 feet. Both ore-bodies found thus far are above the contact, and more of them are expected. In its exploration programme the Colonial management is being guided by the experience gained at neighboring properties, where the enrichments are reported to have extended for approximately 300 feet in length.

At Kirkland Lake the machinery for No. 1 shaft of Continental Mines has arrived and is being delivered on the ground. The cement foundations have been poured, the pole line is up, and underground exploration by means of power drills is expected to be under way by August 15th. Active preparations have been begun to commence sinking No. 2 shaft, to the south of No. 1, from which extensive underground exploration will be conducted, as intimated some weeks ago.

PERSONAL AND GENERAL

Mr. A. D. Miles, who has charge of the Canadian exploration developments for John Taylor & Sons of London, England, has been visiting Porcupine and Kirkland Lake to inspect the work being done on some of the properties under option to his company.

Mr. R. M. Wolvin, president of the British Empire Steel Corporation, was in Sydney for several days last week, inspecting the steel works.

Sir Newton Moore made a tour last week of the steel plant at Sydney and the collieries round about.

Mr. W. D. B. Motter, who is known in Canada for his attempt to concentrate the lean iron ores of Hastings County in the plant of Trenton, Ontario, is now assistant to the vice-president of the Chile Exploration Co.

Mr. J. L. Retallack has returned from the west coast of Africa, where he was engaged in harbour construction, and will resume active mining development in the Kootenays.

Dr. Charles Camsell will accompany Hon. Charles Stewart to the Economic Conference in London, to represent Canada in matters related to the mineral industry.

NITRATE

The production of nitrate in Chile is now approaching normal, and the price for the next year, fixed in May last by the Nitrate Producers' Association, is slightly above that of last year. For the first four months of 1923, exports reached 760,000 metric tons, over three times the quantity during the same period last year.

Portland Canal Having Its Thrills

By ALEXANDER GRAY

It is of more consequence to Canadians that Dr. J. M. Maclaren and H. S. Denny, C. B. E., both of London, are in the Portland Canal mining area of British Columbia, upon professional business, than it is to have the cables convey the disconcerting information that the shares of the Selukwe Company, controlling British Columbia Silvers Corporation, have declined to 10 shillings. Selukwe holds (or held) 902,000 British Columbia Silvers shares. It got them cheap, when they were of problematical value. Other shares in companies with properties near-by in the Portland Canal district were acquired by Selukwe. The success attained by the Premier Gold Mining Company bestirred the locality—and properly so. Under the direction of Engineer Banks, a crosscut into British Columbia Silvers territory intersected what is taken to be a portion of the Premier ore-bearing zone. The values corresponded with those of the Premier. Mr. Banks did not magnify nor minimize them. London broke loose, shook off the bridle, went on the rampage. Selukwe shares, because of its British Columbia share holdings, went to 50 shillings. That they are back almost to where they started from is indicative of what London can do, when conservatism and discretion are set aside.

At one time Selukwe's issued shares were valued in the market approximately at £2,000,000. The Premier Gold Mining Company, privately owned and rarely dealt in, is nominally capitalized at $5,000,000. Odd lots of Premier shares have been traded in at $3 to $4; but that was when the properties were providing profits and it was known they were of undoubted merit.

The contrast between Selukwe and the Premier became acute when the former soared and slumped — with no explanation from the directorate. If Selukwe Directors did not take advantage of their market and provide the company with abundant working capital —if those who bought them on the advance did not take their paper profits — then Canada cannot be charged with responsibility for those steep climbs and nose dives — which may or may not confuse the real issues as to London interests in Portland Canal.

The issues at Portland Canal must not be confused. If there has been a disappointment at the British Columbia Silvers ground, London is at fault. London jumped to the conclusion that the Premier performance was about to be duplicated. The episode does not necessarily mean that British Columbia Silvers are tarnished. It simply means that the World Metropolis was more violent than it should have been. Only speculators shrieked when Selukwe fell.

The Selukwe market was a London creation. British Columbia Silvers' shares were purchased at a low starting price. The difference between the Selukwe and Premier operations is that the latter were an outstanding success before any shares were made accessible to the general public. London billiardists applied the "English" and "reverse English". It remains for Dr. Maclaren judicially to umpire the game. Contrary to the newspaper stories, his special mission was not for the purpose of examining the Indian Mines properties. He has been privileged to inspect the Indian premises; but Montreal and Toronto owners have learned that Dr. Maclaren has to do with the British Columbia Silvers situation.

Several London groups have sought a participation in the Indian. Already there is a London interest in the company. Yet there is no intention to dispose of Indian control — at least until the development programme is further along. Within a few weeks, additional financing has enabled the Indian Company to adopt a more expansive policy. That has priority at the moment. What Dr. Maclaren has to say of the Selukwe areas and the district in general will be none the less interesting as he is the technical adviser of an influential combination of mining capitalists.

Mr. Denny, it is stated by the daily press, is accompanied by Mr. R. B. Lamb, the "eminent mining engineer". That being so, including Dr. Maclaren, London will have authoritative information from a triumvirate whose experiences extend over Australasia, Mexico, Africa, India and Mexico, South America and West Africa as well, Northern Ontario, and now British Columbia. Dr. Maclaren was one of the first to recognize the significance of the geological features of Porcupine and to indulge in projections, the accuracy of which has been sustained by deep development. Certain of his principals in the present instance participated in the Rochester Veteran Claim promotion. Mr. Denny's South African principals are active at Kirkland Lake and have a substantial portion of the Moneta issue. He is now dealing with the Forty-Nine, Daly Alaska, and other Portland Canal properties — unless London's ardor has been chilled by the Selukwe.

As to the Indian Mines, more plant is to be provided by the Canadian owners. If London wishes to join with the Canadians who have brought the Indian so far along, they can do so. The intention is to carry the Indian upper workings throughout the Portland Claims, and to exploit the outcropping ore-bodies on the Indian Morn. Inquiries emanating from London sources leave no reason to doubt their readiness to consider the Indian; but Montreal and Toronto are said to be keener about hanging on than about letting go what may be a very much larger enterprise. They realize, however, that time and working capital are essential factors.

INDUSTRIAL ITEMS

The Canadian Rock Drill Company have opened an office at 170 McGill Street, Montreal, where they carry supplies to fill the requirements of those in Quebec and the Maritime Provinces who use their products.

Powley and Moody Limited, Canadian distributers for the Automatic Transportation Co., Buffalo, N. Y., report that they have just delivered a Type "AA" 2 ton electric locomotive for underground service at the Lythmore, Ontario, property of the Ontario Gypsum Company Limited. They also report that the market is becoming persistently active in connection with storage battery electric trucks, tractors, and engines, and kindred equipment. They have moved their Toronto office recently from 105 Bond St. to 85 Florence Street, at the Brock Avenue subway.

The current number of *Asbestos* asks, "Is it by virtue of the insulating properties of dead air cells that college chaps can go bareheaded summer and winter?"

The Quebec Asbestos Industry

III — The Recovery of Fibre at Present Lost in the Milling of Asbestos

By G. ERNEST BOOKER

As mentioned in a previous article, there are ways of recovering the asbestos fibre that at present is passing out of the mills along with the dust created in the process of milling. This fibre loss is considerable, and in some mills will run as high as 14 tons in twenty-four hours. It will be as well, however, to consider the actual conditions prevailing in the present mills before going into the pros. and cons. of each method of recovery.

Assume, then, for example, a mill that at present is losing 10 tons of fibre per day. This mill will also be emitting probably 12 tons of dust in the same period. The fibre and dust are carried out of the mill and scattered over the surrounding countryside by a large volume of air, which may be anything from 25,000 to 250,000 cubic feet per minute, at the mill. This dust-laden air of course becomes mixed with the outside air as it leaves the mill building, and the dilution renders the settlement by gravity of the solid matter more difficult; thus with the aid of the outside air-currents, the mixed dust and fibre is carried and distributed over a considerable area before even a partial settlement takes place.

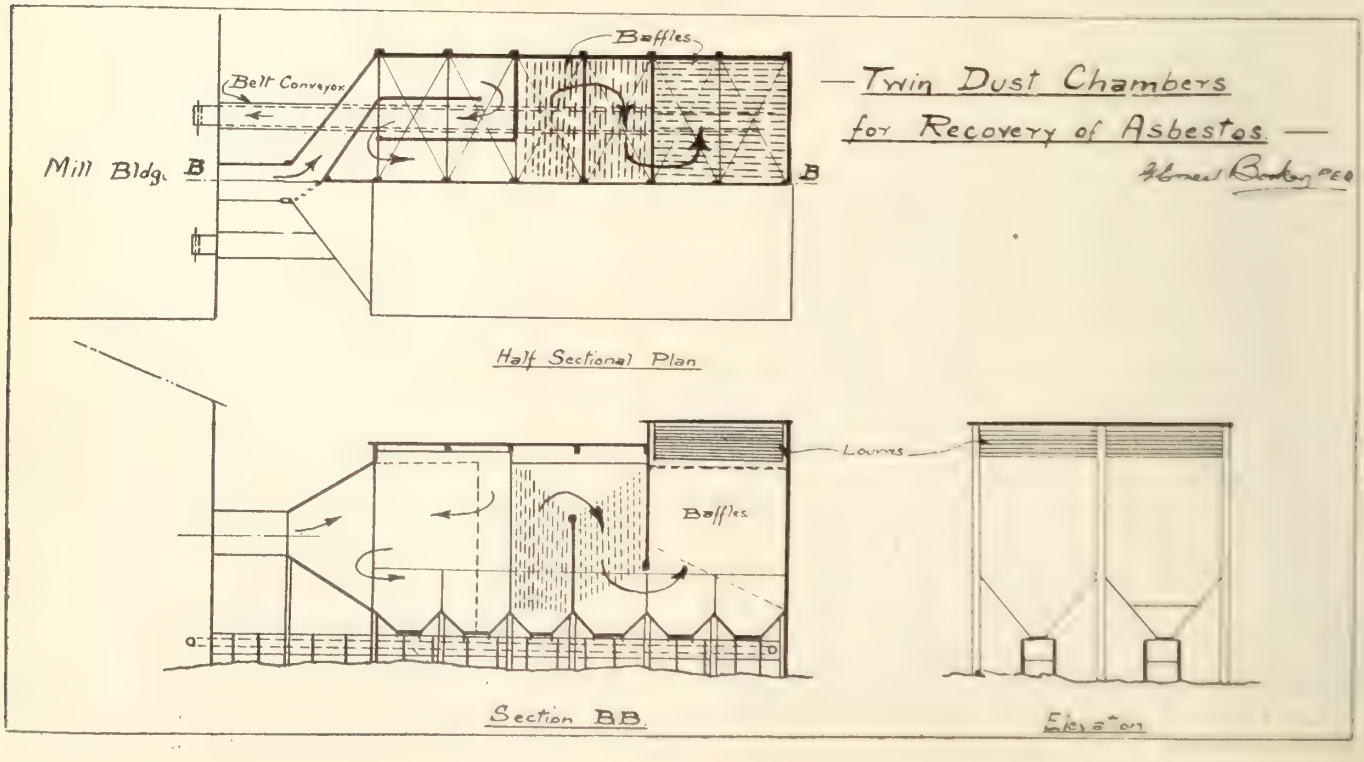
An air current with a velocity of 2,000 feet per minute will pick up and carry with it all light fibre and dust; but even with a velocity of 400 feet per minute very little separation and settlement will take place.

Now the atmospheric conditions prevailing in the locality of any mill are continually changing, most of the changes having a distinct bearing on the quantity of solid matter the air will carry in suspension. These changes are due to temperature and moisture, both of which are beyond human control in the great out-doors.

The effects a change in temperature has upon a mass of air are two in number. Raise the temperature, and expansion takes place, which reduces the denseness of the mass. The increased volume will correspondingly increase the velocity of the mass through ducts, etc. Thus a rise in temperature will tend to cause a settlement or separation of solid matter due to the reduced density of the air; but the increased velocity due to the same cause will nullify the effect.

The moisture or water in suspension in the air is also a factor that bears upon the separation of solid matter from the air. The variations of temperature also affect the power of the air to carry moisture in it; for instance at a temperature of 32° F. the moisture content may be anything up to three-tenths of a pound only, at atmospheric pressure, but at a temperature of 90° F. this may be seven times that amount, or 2.1 pounds per thousand cubic feet. Now the effect of moisture in the air is to make it dense, and the greater its density, the more buoyant it is for solid matter suspended in it. From all of this it would appear that under certain conditions the air is capable of carrying a considerable amount of solid matter in suspension for considerable periods. In other words, its behavior is very much like that of a colloid, if not actually colloidal in the strict sense. It is therefore apparent that the atmospheric conditions do materially affect the gravitation of solid matter suspended in the air, and must enter largely into one's consideration when deciding upon a type of recovery plant.

Let us proceed with the example mentioned above, namely the recovery of the 10 tons of fibre which is known to be carried away from the mill daily, this fibre being suspended in a large volume of air, say 50,000 cubic feet per minute. Reducing these figures to a convenient form one has: solid matter per day — fibre 10 tons; dust 12 tons; total 22 tons, or 30.5 lbs per minute. The air per minute is 50,000 cubic feet. Then the solid matter suspended in a thousand cubic



— Twin Dust Chambers for Recovery of Asbestos. —

feet of air is equal to 0.61 pounds, or, volumetrically, 7.2 cubic inches solid matter in one thousand cubic feet of air.

This sounds like the proverbial "needle in the haystack"; but the greater portion, if not all, of that solid matter must be recovered, because the fibre content is worth almost two million dollars a year to the owners. It can be done, and so, as a beginning, all the dust and fibre-laden air in the mill is collected and brought by means of a duct to the point where the recovery plant is to be established. It is, therefore, from this point that the various ways of recovery will be described and compared with one another from different angles. The methods by which fibre can be recovered have been mentioned previously and they will be considered in the order named.

(1) Settlement by Gravity in a Dust Chamber

Fig. 1 illustrates a type of dust chamber which is probably the most suitable for the recovery of asbestos fibre. The air, fibre and dust are brought to the structure by means of a duct having a cross sectional area of 20 square feet. This, handling a volume of 50,000 cubic feet a minute, will mean that the velocity of the air at the entrance is 2,500 feet per minute. As no settlement or separation will take place at this velocity, it must be reduced by stages to a predetermined minimum. To accomplish this reduction in velocity, the passages or ducts in the chamber are of increasing area throughout, and in the last stages in the chamber a series of baffles are arranged to exert a frictional drag on the air, thereby extracting much of the solid matter still held in suspension. It is, of course, understood that the placing of baffles in a current of air will not materially reduce the velocity alone; in fact, baffles improperly arranged will give the opposite effect, and instead of separation and settlement taking place, the fibre and dust is picked up in places and carried through the apparatus completely.

The construction of dust chambers is a comparatively simple one for the asbestos industry, since no heat or gases exist which would necessitate special precautions; but attention must be given and care taken to see that all walls and partitions are solid and that there are no leaks anywhere. The reason for this is easily seen when one considers that on the two sides of any partition the velocities are different, and so a leakage would disturb the separation and settlement through a considerable area. The chamber illustrated, it will be noticed, is of the twin type, enabling one side to be cleaned out while the other is in operation. Hopper bottoms are provided, which discharge to belt conveyors to convey the fibre and dust recovered to the mill.

The chamber shown is constructed of concrete and gunite and is probably the cheapest form of permanent structure, the estimated cost being from $4,000.00 to $5,000.00, which is insignificant compared with the value of the fibre that such a plant will recover. Assuming a recovery of only 50 per cent, the fibre recovered per annum amounts to 1,500 tons, which at last year's prices means a revenue of approximately $32,000.00.

The actual cost of recovery is not obvious at once, because one is apt to get the idea that, as the separation is secured automatically by gravity, the operating costs are only the interest charges on the plant. This is not so, for before the recovered fibre is marketable it has to be graded and cleaned as well as packed, the cost of which operations must be considered. However, the possibilities of the dust chamber are worth serious consideration, and it may yet be the means of saving some of the asbestos mills from failure.

(To be continued)

ASBESTOS IN THE UNITED STATES

In 1922 the domestic asbestos industry of the United States came to a standstill, according to a statement from the Geological Survey. Only 67 short tons of all varieties of asbestos, valued at $10,120 was produced in 1922, as compared with 831 tons, valued at $336,968, in 1921, and 1,648 tons, valued at $678,231, in 1920.

The Arizona field is the most promising in the United States. The industry there was developed rapidly from a small initial production in 1914 to its maximum in 1920, when it supplied asbestos worth 96 per cent of the total value of the domestic asbestos marketed. This great increase was due to a steady rise in the price of "crudes", which reached a maximum late in 1920 and early in 1921. In 1921 the general business depression greatly decreased the demand for asbestos and prices fell continuously throughout the year. In 1922 the plight of the Arizona miners was made worse by a further decrease in prices, due in part to keen competition with chrysotile from Rhodesia. The prices of "crudes" during the last five months have been remarkably constant, No. 1 Canadian being quoted at $500 and No. 2 at an average of about $290. Each of these prices is about 80 per cent higher than the pre-war figures.

Information received from several sources indicates that there will probably be increased activity in mining asbestos in Arizona in the second half of 1923. Many deposits have been located within the San Carlos and Fort Apache Indian reservations, which were thrown open for entry only in 1921. Some of these deposits are under lease from the Bureau of Indian Affairs and have been partly developed. Outside the reservations there are several deposits, which have been extensively developed but on which operations were suspended in 1922.

One of the chief difficulties in marketing Arizona asbestos has been the work of bringing the producer and the consumer together. To assist in this work the Geological Survey made a canvass of the stocks of Arizona asbestos on hand and for sale on May 22. The returns show that on that date there was ready for shipment 312 tons of "crudes," distributed as follows: No. 1 (including some 1 A), 77½ tons; No. 2, 194½ tons; No. 3 (including some No. 4), 40 tons. Some of these stocks were in lots as large as 130 tons and one included as much as 90 tons of one grade.

ALBERTA REPORT

The "Annual Report of the Mines Branch of the Province of Alberta, 1922", is a comprehensive volume of 336 pages, dealing exclusively with the coal mines and their product. In it the Chief Inspector of Mines, Mr. John T. Stirling, gives, in tabular form, the year's records of the mines and mine accidents, a list of certificate holders, a list of the mines, and a short description of the personnel and equipment of active mines. There is also included the report of the Fuel Engineer, Mr. George R. Pratt, whose activities have contributed largely to the present extended market for Alberta coal and the attempt now being made to sell it in Ontario.

GOLD AND SILVER INQUIRY

The United States Senate Commission of Gold and Silver Inquiry has issued an invitation to all silver producers on the American continents to send representatives to a conference to be held in Reno, Nevada, on September 4th 1923. At this conference questions will be discussed relative to the decrease in the production of silver and gold in the United States and elsewhere, the problems involved in marketing gold and silver, and the effect of the decrease in production upon commerce, industry, exchange and commodity prices. The conference is designed to aid the Commission in preparing a report to Congress, due on January 1st, 1924.

REVISED STATISTICS ON THE MINERAL PRODUCTION OF CANADA, 1922

The Dominion Bureau of Statistics issued on July 23rd the following finally revised statistics on the production of copper, nickel and metals of the platinum group in Canada during 1922.

Copper

The production of copper in Canada during 1922 amounted to 42,879,818 pounds which at the average New York price for the year (19.382 cents per pound) was worth $5,738,177 as against 47,620,820 pounds valued at $5,953,555 or an average price of 12.502 cents per pound in 1921. The decrease amounted to about 10 per cent in quantity and 3.6 per cent in value, and the year's output was the lowest recorded since 1904.

The production included: (a) 29,595,440 pounds contained in blister copper produced during the year, part of which was refined in Canada and part exported to the United States for treatment; (b) 10,841,647 pounds contained in nickel-copper matte produced at Sudbury during the year some of which was exported and some refined in Canada; (c) 57,708 pounds contained in copper sulphate; and (d) 2,385,023 pounds, the estimated recoveries from ores, concentrates and residues exported for treatment.

The corresponding figures for 1921 were (a) blister copper, 32,122,678 pounds, (b) copper in matte, 12,645,391 pounds, (c) copper in copper sulphate, 162,111 pounds, and (d) copper contents of exported ores and concentrates, 2,690,640 pounds.

COPPER PRODUCTION BY PROVINCES

	Quantity Pounds	Computed Value
Ontario	10,943,636(a)	$1,464,477
British Columbia	31,936,182	4,273,700
Total for Canada	42,879,818	5,738,177

(a) Includes some copper derived from speiss and residues from the silver smelters and gold mines of Ontario.

The total production of refined copper during 1922 was 730,000 pounds as compared with 4,286,000 pounds in 1921. During 1922, the plants of the British America Nickel Corporation were idle and the total Canadian production was from the refinery at Trail.

Nickel

Owing to the stagnant condition of the nickel market, the production of this metal in 1922 was lower than in any year since 1904, and compared with 1918, the banner year to date, the production of 1922 showed a decrease to only 19 per cent of the quantity and 16.7 per cent of the value. The output included 17,355,056 pounds contained in nickel-copper matte made by the Canadian smelters treating Sudbury ores and 242,067 pounds, the nickel contents of smelter products resulting from the treatment of silver-cobalt ores.

During the year, 259,569 tons of nickel-bearing ore was mined in the Sudbury district. The smelters treated 314,120 tons from which 17,324 tons of matte was produced. The refinery of the International Nickel Company at Port Colborne was the only nickel refinery operating in 1922. This plant treated 10,340 tons of matte from which 11,065,473 lbs. of metallic nickel and 2,389,840 lbs. of nickel oxide having a reported sales value of $3,140,399 and $389,398 respectively were produced.

PRODUCTION OF NICKEL IN CANADA, 1922

		Quantity pounds
Produced from Sudbury ores		17,355,056
Produced from cobalt-silver ores		242,067
Total production	Quantity	17,597,123
	Computed Value*	$ 6,178,993

* The production was valued at 35 cents per lb., the average New York quotation for nickel in 1922.

Metals of the Platinum Group

The production of metals of the platinum group in Canada for 1922 was derived almost entirely from the nickel-copper ores of the Sudbury district. In accordance with the low production of nickel-copper, the amounts of metals of the platinum group recovered were comparatively small. The actual production figures have been augmented by the addition of quantities produced prior to 1922 but reported for the first time in that year.

The production was valued at the average New York quotations for the year which were as follows: platinum $97.618 per fine ounce, palladium $65.00 per fine ounce and osmium group $80.00 per fine ounce.

METALS OF THE PLATINUM GROUP, CANADA, 1922

	Platinum	Palladium	Rhodium, Osmium, Ruthenium & Iridium
Produced by Canadian and United States nickel refineries from Canadian ores .. fine ozs.	458	724	391
Value	$44,709	$47,060	$331,280
B. C. Placers .. .. fine ozs.	11	...	1
Value	$ 1,074	...	80
Total for Canada .. fine ozs.	469(a)	724(b)	392(c)
Value	$45,783	$47,060	$331,360

(a) includes 282 ounces palladium
(b) includes 388 ounces palladium
(c) includes 266 ounces of others

Platinum not reported previous to 1922.

RAPID HOISTING ON RAND

A new electric hoist at the Randfontein Central Gold Mines raises a load of 10,000 pounds from a depth of 5,000 feet at a speed of 4,000 feet per minute. Fifteen seconds are allowed for acceleration, ten for retardation, and five for loading and tripping. The speed is controlled automatically as to acceleration, maximum and retardation. Dynamic brakes are used, which turn the energy let loose by retardation into useful electric energy.

CHECK-OFF REQUIRED

Employees being signed on again by the Dominion Coal Company are required to sign the U. M. W. A. check-off anew. It is evident that those who intend to break away from the U. M. W. A. will not be employed by the Company.

At the Wheal Busy mine in Cornwall, formerly worked for tin, a new shaft is being put down to develop a vein of arsenical ore, determined already as 4 to 8 ft. wide and 300 ft. long, with an average of 15 to 20 per cent. arsenic.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

South Lorrain. — McKinley-Darragh has taken an option on the Paul claims in South Lorrain, on which a discovery was made recently. The vein is reported to be about 18 inches wide and to carry fair values in silver. The company has let a contract for the sinking of a 50-foot shaft. Development in South Lorrain continues promising, and both the Keeley and Mining Corporation are obtaining a substantial production. Sinking operations will shortly be started on the Lorrain Consolidated, as well as on the Maidens property, which is under option to interests associated with the Keeley, while the ground under the bed of Trout Lake will also be explored.

Cobalt. — Milling has been started on the Beaver, which is being operated by the Coniagas. The mill has been very largely rebuilt and now has a capacity of 150 tons a day. A substantial tonnage of ore is broken on the stulls underground, and several discoveries have been made within the past few months that give promise of a supply of ore for some time to come. The lower levels of the Beaver are being unwatered through the Temiskaming shaft, and when this has been completed, exploration will be started on the lower contact of the diabase sill. Some years ago a large vein, carrying encouraging amounts of silver, was encountered at 1,200 feet, and it is on this vein that work will be concentrated.

The Colonial Mine is preparing to resume shipments of mill rock to the Mining Corporation plant. A new vein was found recently to the north of the shaft at the 935-foot level, and carries some silver.

A new level has been opened at a depth of 685 feet in the new Violet shaft of La Rose, and the vein should be encountered within a few days. On the 635-foot level drifting operations disclosed a body of high-grade mill ore, in addition to a fair amount of high-grade. The Company is shipping regularly to the Mining Corporation's mill.

Porcupine. — Both units of the Lower Sturgeon hydro-electric plant are now in operation, and for the first time in many months there is a surplus of power in Porcupine. The Northern Canada Power Company has about 3,500 h.p. available which is not being used, but this will be absorbed by the Hollinger as its milling capacity is increased, and other companies will no doubt take more. A very considerable rainfall during the past month has resulted in the storage basins on the Metagami River being filled up and it is expected that no further power troubles will be experienced for the balance of this year. The power company believes that it will be able to provide sufficient power until the Quinze development is completed in 1924; but it is probable there will be another shortage next winter. Although the case between the Hollinger and the Northern Canada Power Company has not yet been settled, the Hollinger is going ahead with the development of its power on the Abitibi River and has let contracts calling for the development of 20,000 h.p., the estimated cost of which is approximately $3,000,000. The Great Northern Power Company is delivering power to the Davidson and in a short time will also be supplying the Newray and Night Hawk Peninsular mines.

The Dome is running a crosscut on the 12th level to intercept the ore-body recently encountered by a diamond drill. It was reported that the drill had cut 50 feet of $12.00 ore lying to the south of the intrusive porphyry mass, which it was feared might cut the hanging wall ore-bodies off below the 12th level. The company is treating over 1000 tons a day, and is producing at the rate of approximately $400,000 a month. It is stated that as soon as the new stock certificates are printed, the present stock will be split and shareholders will receive two shares of the new stock for one share of the old.

At the Vipond the new vein being developed on the 300, 400 and 500-foot levels, has been found on the surface. This ore-body is of considerably higher grade than the general average of the mine, and will enable the management to maintain a milling grade of at least $10.00 per ton. It is expected that the alterations to the mill will be completed by the first of December, when treatment at the rate of 150 tons a day will be commenced. A Diesel oil engine will be installed in the mill to insure continuous operations.

At a shareholders' meeting of the Davidson Mines, held in Toronto recently, the directors announced that they proposed to begin work immediately on the sinking of a 1000-foot, three-compartment incline shaft. It was also stated that as soon as possible, work will be commenced on the construction of a 500-ton mill. Diamond drilling is stated to have had very satisfactory results. The company has approximately $550,000 in cash on hand, although this is in the nature of an advance and constitutes an obligation on the part of the Porcupine Davidson Company.

Larder. The Crown Reserve is understood to have disposed of 150,000 shares of treasury stock at 60 cents a share, which will be ample to finance the operations of the company for some time to come. The directors have decided to do 1,000 feet of drifting on each vein at the 350 and 550-foot levels. On the Associated Goldfields property, adjoining, a total of 3,400 feet of drifting has been done on four levels, most of which is in ore. The vein has a maximum width of 35 feet, and the grade is understood to be about $8.00.

Kirkland. In Kirkland Lake, operations are proceeding on a number of non-producing properties. At the Harvey-Kirkland, cross-cutting is being carried on at the 200-foot level, which is expected to cut several veins. As soon as the new mining equipment has been installed, the shaft will be continued to 400 feet.

Negotiations have been concluded for taking over the Townsite property by John Taylor & Sons, of London. One or two diamond drill holes will be put

down to determine the geological features, and a shaft will then be sunk to a depth of several hundred feet.

Operations have been commenced on the United Kirkland, the control of which recently changed hands.

The veins recently found in the 350 and 450-foot levels of the Montreal-Ontario are being developed rapidly. No information has been given out regarding the values found, but they appear to be sufficient to enable the company to sell a considerable amount of stock.

Underground operations at the Bidgood have been stopped on account of a lack of financial resources. It is rumored that the Tonopah Mining Company is negotiating for an option on the property.

Rouyn. — A Montreal company is trying to sell shares in the Rouyn Gold Mines by means of ridiculous statements and advertisements. While this district in Northwestern Quebec is one of considerable promise, there is nothing to justify the extravagant claims being made. The most important discovery in the district is on the Powell property, which is under option to the Noranda Mines. The main vein has been traced for a considerable distance, and two shoots of commercial ore have been found on the surface. The company has started a diamond drill to work in an effort to link up these two ore-shoots, and if this is successful, sinking will be commenced. Surface work on the Noranda has shown that the most valuable discoveries are toward the south end of the property On the Hammil group, lying to the north of the Noranda, a considerable amount of diamond drilling has been done, and it is understood that the results were not particularly favorable. Very little news is coming from Rouyn at the present time, and there is a tendency on the part of the prospectors to keep the news of any discoveries quiet. Claims in Quebec are up to 200 acres each in size, and the staking was very poorly done, so that boundary lines are often a matter of conjecture. Prospectors are disinclined to report discoveries, when it may be found afterwards they are upon an adjoining claim. This condition of affairs will continue until a good deal of surveying has been done. The bush in the vicinity is very dry, and it is feared that fires may break out again. The water in the Kinojevis river also is very low and a great deal of difficulty is now being experienced in getting into the district.

NOVA SCOTIA

A Vexed Question Now Settled — *The Canadian Mining Journal* for months past has been pointing to the only satisfactory culmination of the long drawn-out labor agitation carried on by labor leaders who seemed bent on the destruction of the coal and steel industry of Nova Scotia. It was clear to the *Journal* that all the miners of Nova Scotia could not follow their leaders through with the mad policy they had marked out for themselves and for the members of the organization. It was apparent that some day something more silly than usual would be done, and the end would be in sight immediately. No more senseless or futile strike was ever attempted than that brought on in the Cape Breton and Pictou collieries last month, and few have had such a sudden ending. President Lewis, in one fell blow, dealt with the offending officers and swept them out of the way. Their places were filled with provisional officers, and fourteen experienced organizers were brought in from the colliery districts of the United States to re-organize District No. 26. This last step was not necessary, for it took the Nova Scotia miners only a few days to realize the true state of affairs and to fall into line. The change of sentiment seemed rapid, but in reality there had been no previous desire on the part of the majority of the workmen of Nova Scotia to stop work, which they did only against their own better judgment

Leaders have Corrupted Morals of Miners — Of the labor officers who brought the men to such a stage, we have little just now to say. They are better left to the tender mercies of their own thoughts of what they now are and what they might have been. But something ought to be said to the average workman for the part he played in the affair, which was, to say the least, a most dishonorable one. I have heard it said a thousand times that among the workmen of Nova Scotia there are many fine men. That may be so, but men are not fine if they are not honest and if they allow other men to cause them to violate their word of honor. There was a time in the history of trade unionism when the officers and members of a Nova Scotia labor organization, the Provincial Workmen's Association, fought long and bravely to maintain inviolate the agreement they had made with the Dominion Coal Company, and in this they were ably backed up by the public, and won out. It is remarkable, however, that the very labor organization that assailed them at that time and had placed the now deposed leaders in the forefront has had to turn round and undo all their past labors. The United Mines Workers then taught the late leaders that it was a righteous thing to break an agreement, and spent over a million dollars vainly to prove it. In that great and fruitless effort they struck a blow at the conscience and at the common honesty of the mine workers of Nova Scotia. They are, therefore, equally responsible with the late district labor officers and with some of the rank and file for this moral degeneration.

The Silent Majority are Culpable — That the International Union later on recognized their mistake, and made an honest effort to remedy it, is well known. But there still remained in the minds of the workmen the experience of the past, when "scraps of paper" were torn up with delight with the intention of harassing the Dominion Coal Company. That the sense of honor had not completely died out of the breasts of the miners of Nova Scotia was made evident quite recently by the smallness of recent vote to strike in face of the agreement. Out of 13,000 men only a little over 3,000 voted in favor of breaking the agreement and going out on strike; the other 10,000 being either opposed or unwilling to violate their conscience remained away from the polls. The 2,500 voters who openly opposed the strike formed a nucleus of active men to whom it was afterward found possible to add the silent and, for the time being, passive majority. But it would have been infinitely better and more to their credit had all these men voted against a strike during the term of the agreement, and then turned to their leaders and dealt with them summarily for proposing any violation. It can truly be said of the many

who stayed quietly at home that they were ready to wait and watch the outcome of the struggle and to take what benefit was coming from the strike and then shout the praises of their leaders, who at the expense of the honor and integrity of the members of District No. 26 had again triumphed. Such are not the men who build up a strong organization of any kind. What is needed most today is common honesty. Men who in private life pride themselves in keeping their promises should not be less loyal to their word given in concert. The man who fails to respect his word of honor shows disrespect to himself and repudiates the principles on which the foundations of civilized society rest. Faith is a small word, and smacks of theology; but there must be more of it in the business relations of all engaged in the steel and coal industries of Nova Scotia, if these are to be operated on a successful basis.

There will be no longer any doubt in the minds of the miners as to what the Coal Company can do when a strike takes place in the summer time. This season was selected as the best time for the miners to win. But they have learned that power plants can be kept running, fans and pumps operating, and many other things kept going without their aid. They have also learned that, with proper protection, coal can be loaded at the coal piles and shipped from the piers at Sydney. It would have been better for the workmen had they learned this long ago, for they might then have escaped a strike that has been disastrous to their present hopes, though it doubtless has been a blessing in disguise.

BRITISH COLUMBIA

Alaskan Coal Production. — E. L. Bedell, president of the Alaska Bituminous Coal Co., announces that 14,000 acres of coal-bearing land situated on Moose Creek, Alaska, are to be exploited by a group of business men of Anchorage, Alaska; that outside shipments are being deferred until next April because of the necessity of supplying substantial quantities to the Alaskan railroad in the next three months; that a spur from the Matanuska branch of the railroad to the coal properties will be completed by the month of September; and that, as the coal is of high quality, averaging better than 12,000 British thermal units with about twelve per cent. ash, it is confidently expected that a large market can be built up with the cities of Portland and San Francisco on the Pacific Coast. The Company plans to purchase two ships of not less than 500 tons, one of which will be used for supplying the coal requirements of Alaskan coast centres and the other to carry coal to Oregon and California. Twenty thousand tons is said to be blocked out and no difficulty is likely to be experienced in reaching a daily production of 1,000 tons.

John L. Lewis Advises Miners. — John L. Lewis, president of the international body of the United Mine Workers of America, has instructed Wm. A. Sherman, president of District 18, U. M. W. of A. (Eastern B.C. and Alberta) that it would be well to withdraw the call issued for a general labor conference in Western Canada to decide upon a policy for sympathetic action in support of the striking miners in the Province of Nova Scotia. Mr. Lewis stated that the miners of District 18 must carry out the rules and policy of the U. M. W. of A. and fulfill their obligations to the Operators under the agreement in force. At the time of writing Mr. Sherman had not withdrawn the call but had promised a statement at a later date.

Dr. Camsell Summarises Coal Situation. — With reference to Canada's fuel supply, Dr. Charles Camsell, deputy Minister of Mines for the Dominion and Chairman of the Dominion Fuel Board that went thoroughly into the problem in recent months, recently said that there was nothing to add to the Committee's report. Generally it had been found that the coal fields of eastern Canada could take care of the requirements of the maritime provinces, of Quebec, and a small part of northern Ontario; that the prairies, from a point near the western limits of the great lakes, and British Columbia were independent, having supplies within their boundaries that were adequate; but that there was a gap between the east and the west, comprising the greater part of Ontario that, under present conditions, must be dependent upon coal imported from the United States. The investigation had served a good purpose. It had made clear the situation as to the fuel resources and fuel requirements throughout the Dominion and, with a thorough grasp of the problem, it should be easier to regulate distribution in the future in the best interests of all consumers should regulation be necessary.

GOOD MEDICINE

The following pen picture of Granby Bay and other parts of Alice Arm on the northern British Columbia coast, is from the *Granby News*, the little weekly that helps to make Anyox a model mining town:

To appreciate thoroughly the environs of Anyox, a motor boat is an essential. We have no land ways along which our feet may wander, our outings being confined to stretches of water hard to duplicate anywhere. On these we may roam where our fancy wills if the craft is a stout one and the "kicker" dependable. It is not everyone, however, who is fortunate enough to possess a hull seaworthy enough to bundle the family aboard on a Saturday afternoon and get far enough away from home to appreciate fully some of the wonders of this great north country. To the owner of the motor boat, any little cove is a haven and the forests stretching down to tide-water places of enchantment. For those who are not regular contributors to the coffers of the oil kings, they have an opportunity of indirectly contributing on occasion, while doing themselves and their families much good. Now this little article is not in the nature of an advertisement, it is purely gratuitous and well worth the price at that. Not having a boat of your own and lacking a friend who might possess such a thing, it will more than repay you in dividends of red corpuscles for such a thing, for the small outlay exacted for your transportation any Sunday morning to Alice Arm, where you may revel with nature at its best in the valleys of the Illiance or the Kitsault. If the writer were a Doctor, he would prescribe this trip occasionally for everyone and frequently for some. The salt air of the water trip and the pine-scented air of the big woods, through which many trails wind is good medicine, and yours for the taking. A walk along the Dolly Varden road bed to the second falls is recommended. Boil the "Billy" there, and it will surprise you especially if the wife and kiddies are along, how little there will be left of that luncheon, which looked

so big when you left home; and when you return to the quaint little town nestling on the flats of the Kitsault, drop into the wee place of the shoemaker, and very likely with your icre cream there will be a generous quantity of luscious strawberries freshly gathered from the garden behind; and before you leave, if you hint at coming from Anyox and remark on the beauty of the blooms outside the window by which you are seated, maybe you will be presented with a bouquet of bachelor's buttons, Canterbury bells, candy tuft, yellow faced susans and petunias. Suggestive of old gardens, are they not; and sounds old fashioned. And all in a mining camp, too.

ALASKA GOLD MINING IN 1922

According to a statement given out by the Department of the Interior, Alaska has produced in all $335,526,460 worth of gold and $8,833,922 worth of silver. Of this gold, $230,506,992 has been taken from placer mines, $103,227,434 from lode mines and $1,792,034 from copper mines.

In 1922 $4,395,000 was recovered from Alaska placer mines and $3,015,669 from lode mines. In the summer 507 placer mines, employing 2,150 men, were operated, and of these, 120 mines, employing 402 men, had also been operated the previous winter. The total number of large and small auriferous lode mines operated in 1922 was 28.

These figures are taken from the annual report of Alfred H. Brooks, of the Geological Survey, now in preparation. In this report he states that there is geologic evidence of the occurrence of extensive auriferous lode deposits in Alaska and that a rough estimate, based on the best data available, indicates that the Territory still contains some $350,000,000 worth of placer gold.

A NEW USE FOR KIESELGUHR

There occurs in the former lake of Jallaso in Sweden, now drained, a large deposit of kieselguhr containing a natural admixture of 20 percent of bituminous matter. It has been found that this raw material can be pressed directly into plates or blocks eminently suited for building purposes. By a single means these plates or blocks are made impervious to water, and this quality, in addition to their insulating quality, makes them extremely valuable for structural purposes. A new firm, the Swedish Kieselguhr Company, has undertaken the manufacture of this material in a plant with an initial annual capacity of 100,000 square metres of insulating plates. It is expected these plates will be used principally as an interior covering in stone and brick buildings.

OIL FROM TAR SANDS

It is reported that the Athabasca Petroleum Products will build a 250-barrel oil refinery at Fort McMurray this summer, for the extraction of petroleum products from the Athabasca tar sands. They are now moving their equipment to Fort McMurray, where they will start operations about September 1.

POSITION WANTED — A Canadian Mining Engineer, graduate of Canadian University, specialized in the geology, development and operation of iron mines on a large scale in the Western States, desires to return to Canada to follow up the iron industry. Can give best references. Apply Box 602, Canadian Mining Journal, Gardenvale, Que.

FOR SALE

Entire Equipment of our Concentrating Plant at Black Lake, Quebec

including:

Three (3) Gould Triplex Pumps
Two (2) Hardinge Mills
Two (2) Farrell Crushers

"Every man owes some of his time to the upbuilding of the profession to which he belongs"

Theodore Roosevelt

All Shoulders To The Wheel!

So much interest and close co-operation has already been evidenced that the success of

AMERICA'S MOST IMPORTANT INDUSTRIAL EXPOSITION

is assured, and there is every indication that this year's Exposition will be the greatest of its kind in the country, if not in the world.

9th NATIONAL EXPOSITION FO CHEMICAL INDUSTRIES

GRAND CENTRAL PALACE, NEW YORK

SEPTEMBER 17th-22nd

(The Only Chemical Exposition To Be Held This Year)

Everyone who knows what a tremendous factor chemical knowledge is to every industry "owes some of his time" to directing the attention of executives to the great benefits to be anticipated by a visit to this Exposition. There is no industry in the country that cannot be helped by the ideas to be given at this Exposition.

One of the important features will be the presentation of ways and means to enhance labor productivity. The utilization of waste products will also be given special attention.

Exhibitors are making elaborate plans to have this year's exhibit surpass any showing made during previous years.

For further information address National Exposition of Chemical Industries, Grand Central Palace, New York

Ontario's Minerals

PROVINCE OF ONTARIO

DEPARTMENT OF MINES

Hon. H. MILLS, Minister of Mines

Mineral Areas.

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favorable for the occurrence of minerals, 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals.

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario:—actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production.

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1921 to be worth $48,128,387, of which the metallic production was $27,574,202.

The following figures show the rapid growth of Ontario's mineral industry by five-year periods since 1891:

Year.	Value.	Year.	Value.
1891	$4,705,672	1906	$22,388,383
1896	5,235,003	1911	41,976,797
1901	11,831,086	1916	65,303,822

Dividends.

Dividends and bonuses paid to the end of 1921 amounted to $23,140,734 for gold mining companies, and $84,388,185 for silver mining companies or a total of $107,528,919.

Mining Regulations.

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office.

The Provincial Assay Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

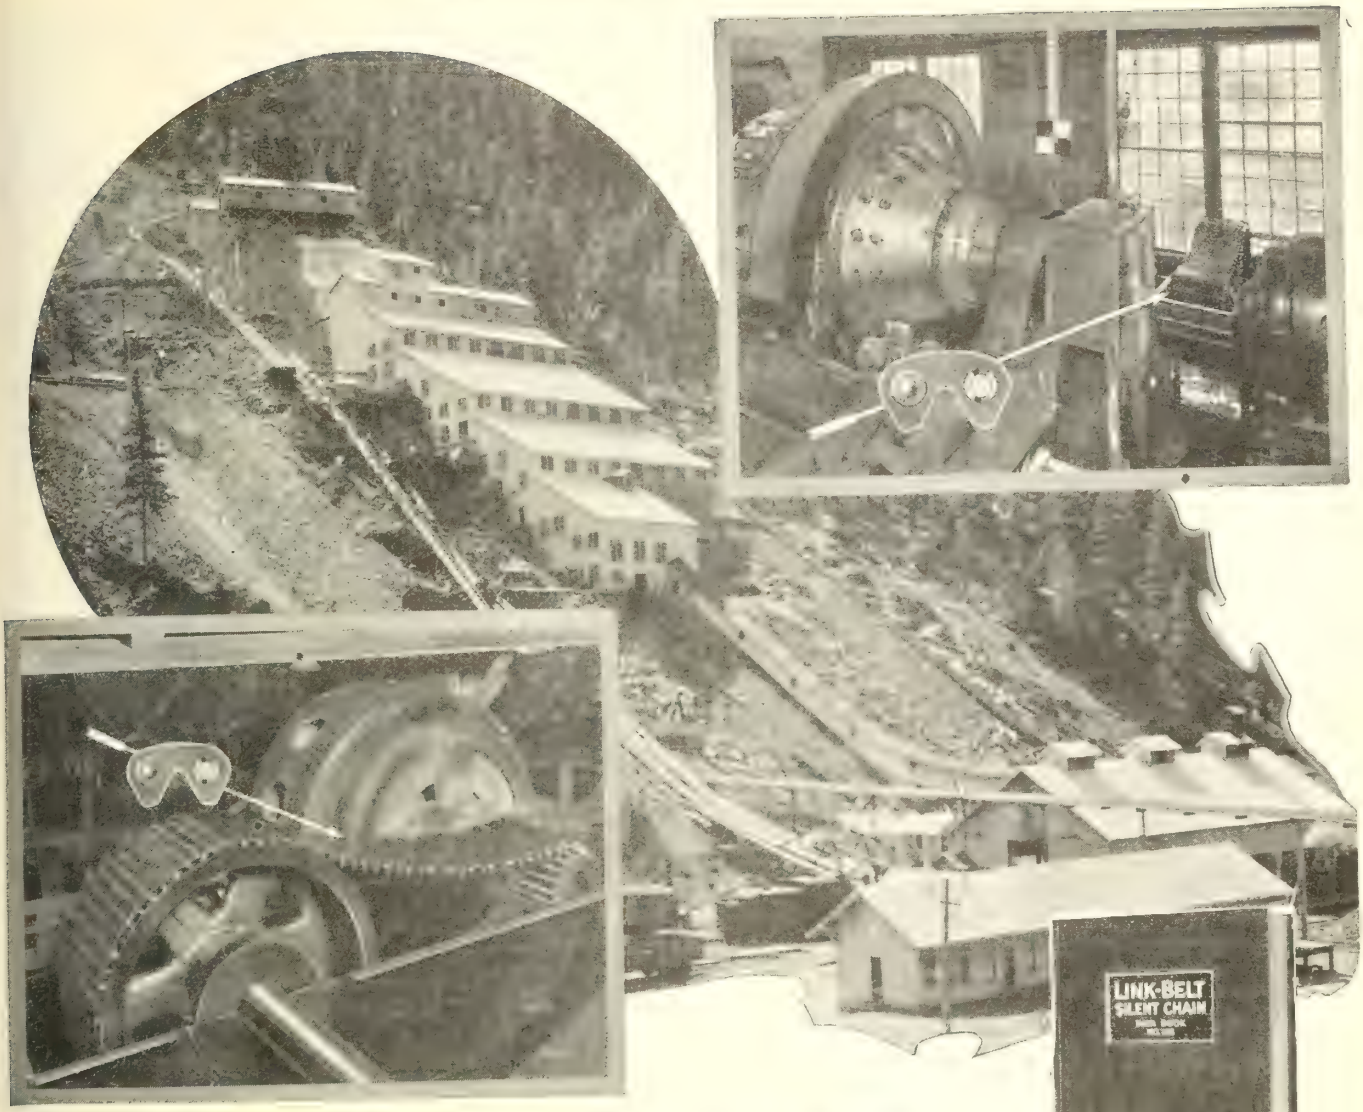
Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Publications.

For list of publications, illustrated reports, geological maps and mining laws, apply to

THOS. W. GIBSON,
Deputy Minister of Mines,
TORONTO, CANADA.



Efficient Power Transmission

at the Engels Copper Co., Engels, Calif.

Efficient, reliable transmission of power means more than elimination of trouble; it really means increased production. Uninterrupted operation of blowers, grinders and conveyors reflects itself in the output records of the mill.

That's why, after experience with many types of transmission, the Engels Copper Company determined upon using Link-Belt Silent Chain in their mill four years ago.

Send for Data Book No. 125—a handbook on silent chain practice. Return the coupon.

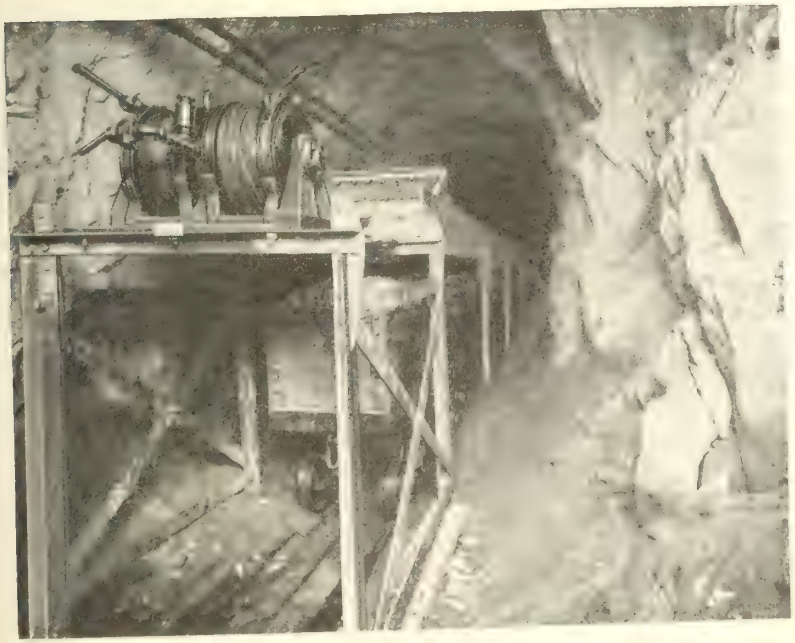
"SLUSHING" with TURBINAIR HOISTS

(Trade Mark)



You can speed up your development work by loading your cars from a movable platform like the one shown here in a Butte Copper Mine.

A Sullivan Turbinair Double Drum Hoist

hauls the broken rock or ore in a self-loading scraper from the breast up an incline to the platform, where it is dropped into the cars below. Some platforms have storage space, so that "slushing" continues while cars are being spotted.

Hauls to 150 feet are made economically before moving the platform closer to the breast. In the Butte mine shown two men drill, blast and muck out in an 8-hour shift. 45 to 60 cars (14 cu. ft. each) are loaded in 2 to 2½ hours.

This is only one adaptation of Sullivan Turbinair Hoists for "slushing". Others are described in detail in our new Bulletin No. 676-D.

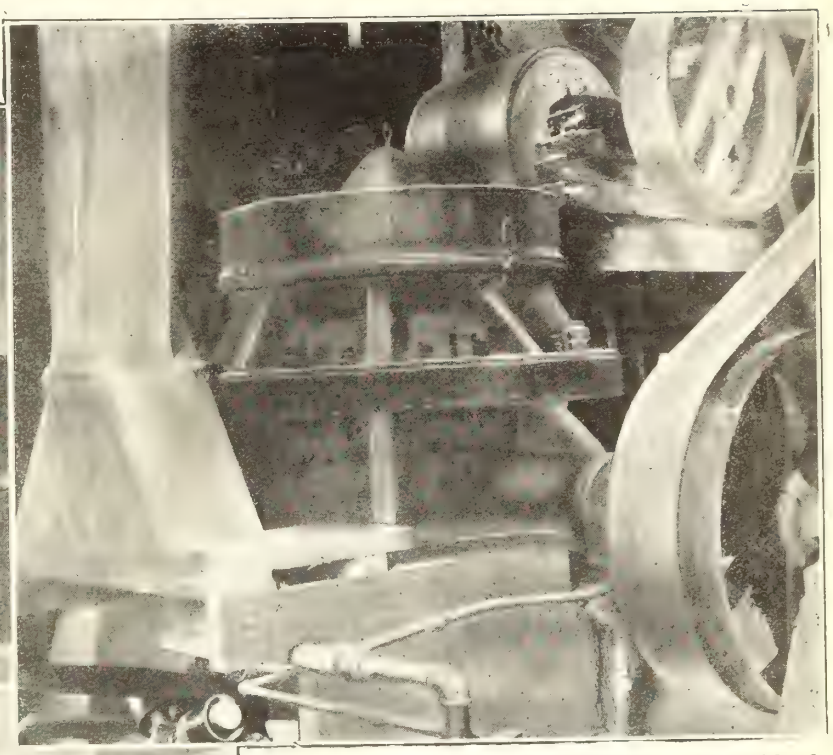
No. 3 Telsmith Reduction Crusher in a large Western Trap Rock Plant



No. 2 Telsmith Reduction Crusher at Kirkland Lake Gold Mines, Kirkland Lake, Ontario.

"Load it to the Muzzle"

It works best with choke feed

There are many secondary crushers, but the others will take only a certain amount of rock at any one time. If fed a little too fast the belt flaps, the crusher stalls and you spend half an hour digging out the rock.

Of course, there are scores of feeders — plate feeders, apron feeders, fleeting rolls, etc., but there is just one crusher that does not need these frills—the TELSMITH. It works best with a choke feed. You can cover it with ten or twenty feet of rock and it will eat its way through, with bolts tight, oil cool and bearings smooth.

Its simple all-steel construction also protects you from break downs or tramp iron troubles—without fuss or bother.

Write for bulletins and a list of users who can tell you all that is good, bad or indifferent about the "TELSMITH."

The Mineral Province of Western Canada

Has produced Minerals valued as follows Placer Gold, $76,542,203; Lode Gold, $109,647,661; Silver, $59,814,266; Lead, $51,810,891; Copper, $170,723,242; Zinc, $24,625,839; Coal and Coke, $238,289,565; Building Stone, Brick Cement, etc., $36,605,942; Miscellaneous Minerals, $1,358,839; Making its mineral production to the end of 1922 show an

Aggregate Value of $734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive $94,547,241; for five years, 1896-1900, $57,605,967; for five years, 1901-1905, $96,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for 5 years 1915-1920, $189,922,725; 1921, $28,066,641; for the year 1922. $35,158,843.

Production During last ten years, $339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

VICTORIA, British Columbia.
THE HON. THE MINISTER OF MINES.

PROVINCE OF QUEBEC

MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

MINER'S CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONORABLE J. E. PERRAULT,

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

Assisting in the Development of the Mining Industry

It is essential that the peculiar banking needs of those engaged in the exploitation of Canada's natural resources be met with special facilities.

The Imperial Bank, ever a constructive element in the progress of Canada, long since realized the need for interested financial service to enable the proper development of the mining industry.

By opening branches throughout the mining districts and continually adding to them, as necessitated by expansion, this Bank has materially assisted in the development of the industry throughout Canada.

Those whose business is mining will find our facilities adequate and our knowledge of conditions valuable.

:-: EDITORIAL :-:

GOOD AND BAD ADVERTISING

Both the Premier of Ontario and the Minister of Mines have stated publicly that they intend to let the world know the facts about the province's minerals. "Our light will no longer be hid under an agricultural bushel!" says Mr. Ferguson in an interview published in the *Journal* last week. "We must let the world know that the North will produce immense quantities of precious metals just as surely as the prairies will produce wheat," says Mr. McCrea in an interview published in the Toronto *Star*. Good! The more widely the facts of our mineral resources are known, the more rapidly will they be used, and the wider will be the market opened to them. We need capital, labour and enterprise combined to open up our mineral districts, and we can rest assured that the new Ministers of the Crown will follow up their stated intention with vigorous action.

Our mineral resources need advertising — of course they do. But they need good advertising, not bad. It is not long since a responsible public official stated boldly and without qualification that the northward extension from Cochrane of the Temiskaming and Northern Ontario Railway would open up a mineral district as productive as that to the south. He did not know what he was talking about, and had not taken the pains to consult those of his subordinates who knew the facts. That was bad advertising. We can trust Messrs. Ferguson and McCrea, both of them personally acquainted with the mining industry, to avoid any errors of that variety.

There is another form of bad advertising that is much more dangerous to our mining industry and much more difficult to control. Every time an investor is "stung" by a wild-cat mining scheme the industry loses a supporter, and gains either an out-and-out enemy or a cynical observer whose influence is worse than that of an enemy. The crooks who are formulating these schemes and "putting them across" are legion, and their number is increasing daily. Their dupes are unbelievably numerous, and are to be found in all walks of life. Among them are numbered thousands of men, shrewd and competent in their own lines of business, in addition to the greedy, the helpless and the foolish upon whom the stock-jobber depends for his steady income. The western provinces and the maritime provinces have adopted measures to palliate this evil. The Premier of Quebec has expressed his intention of regulating the issue of stocks, particularly mining stocks, in such a way as reasonably to protect the investor. Ontario has a "Blue Sky" Act on the statute books; but its application to mining stocks has been deferred until September 1st, and then it can be put in force only by order-in-council.

When the bill to regulate the rate of securities was before the Ontario Legislature last spring, Mr. McCrea, then a member of the Opposition, was an outspoken critic, and one of its chief opponents. He spoke of it as an imperfect piece of legislation, which of course it is, in common with all experiments in regulation. Not only this, but he condemned it as against the interests of the mining industry in general — for reasons we have still to discover.

Mr. McCrea is now in a position to regulate or even to control the principal advertising Ontario's mining industry will receive in this and all other countries— that resulting from the sale of securities based upon Ontario's mineral resources. If the prospectuses and advertisements soliciting capital for investment are statements of the truth, Ontario will benefit immensely, for the truth, as Mr. McCrea remarks himself, is sufficient inducement to draw widespread attention. If, on the other hand, exaggeration and lies are spread abroad publicly as representing our mining industry, the truth will never overtake them, and inevitably the industry will suffer.

It is obvious that the present regulation of the sale of mining securities is inadequate. The late Government of Ontario made an attempt further to regulate it. Mr. McCrea and other members of the present government considered the attempt misguided and opposed it. Now it is up to him and his colleagues so to modify the present Act as, at one and the same time, to conform with their own judgment and to protect the Canadian citizens whose best interests they have sworn to serve.

Prompt action is required, for the mining industry of Ontario is still the victim, daily, and needlessly, of the worst sort of advertising.

EXPLORATION IN GILLIES LIMIT

It is interesting to note that there has been, during recent months, a decided recrudescence of interest in the Gillies Limit. In the early days of the Cobalt camp, when this timber limit, adjoining the productive area on the southwest, was closed to prospectors in order to ensure protection from fire, it was supposed to contain fabulous riches. Development dis

closed little of value. At the Provincial Mine, discovered by employees of the Ontario Bureau of Mines and operated by them for a short time, there were found some pockets of high-grade ore in a well-defined vein of unusual width. A number of adjoining properties showed similar patchy values. The report that further bunches of high-grade ore have been disclosed by exploration in the Provincial Mine now in progress may presage the discovery of payable ore.

It is rumoured that the Mining Corporation intends to explore seriously some ground about three miles southward from the Provincial. There occurs here a sill of diabase much like the one that brought the silver into the Cobalt veins. Though no workable values have been found in connection with this more southerly sill, it is quite possible that underground exploration will disclose a third area of silver deposits similar in character to those at Cobalt and in South Lorrain.

A DANGER SIGNAL

On September 1st the Ontario Department of Mines will lose its Assistant Provincial Geologist. On that date Mr. Cyril W. Knight will take up his new work with the Nipissing in Cobalt. Ontario will lose a most effective public servant; but the Province's mineral industry will retain the services of one who has contributed much to its progress in the past, and will continue in his chosen sphere of work in a private capacity.

Mr. Knight has been on the staff of the Ontario Department of Mines almost continuously since his graduation from Queen's University in 1903. He assisted Dr. Miller to make his first map of the Cobalt district in 1904, and has followed in detail the fortunes of our famous silver camp ever since. In addition he has had a varied and well-rounded experience in the other mining camps throughout Ontario. Three years ago he was authorized to make a thorough and final examination of the productive area at Cobalt. Many thought of this as merely an *ante mortem* examination, interesting more in the light of a historical record than as of present utility. But Mr. Knight was much too wise a physician to give up hope while life still remained in the patient. His researches of the last three years, both on the surface and underground, based upon his previous intimate knowledge of the whole area and of similar geological occurrences throughout the world, have led already to the re-making of an old mine, the Colonial. It seems probable that numerous other mines will be developed or will be prolonged in life as a result of the clear-cut conclusions Mr. Knight has formulated and stated publicly as a result of his studies.

It is as a result of Mr. Knight's demonstrated ability to see farther into the rocks than other men that Nipissing Mines have engaged him to direct their exploration. While the veins were to be discovered on the outcrop or by following them underground in the ordinary way, the knowledge of the mining engineer was sufficient. Now there is required knowledge in addition to that possessed by the average mining man. The southeastern part of Nipissing's large acreage in the heart of the Cobalt district is covered by the diabase sill from whose intrusion the silver veins originated. The sill outcrops diagonally across the property from southwest to northeast and dips toward the southeast. The deep-buried contact requires exploration, and as underground prospecting is decidedly expensive, it will pay to have, at almost any price, the best qualified man to direct it. The Nipissing directors have decided that Mr. Knight is that man.

This brings up once again the vexed question of the remuneration paid to technical men in the public service. Rarely are their salaries in proportion to their services, particularly in the case of juniors, and often the pay is not sufficient to support a family in reasonable comfort. The scientist in public employ, unless he has a private income at his back, must take the satisfaction of work well done in the service of science as part of his payment. Only an enthusiast can do this. The fact that there is a substantial remainder of capable geologists in the public employ is a tribute to the compelling attraction of their chosen calling.

While it is an admirable arrangement that the various Departments of Mines should constitute themselves schools for the training of young geologists for the direct service of industry, the depletion of the ranks of highly trained public servants can be carried too far. When, as in the case of Mr. Knight, a private company bids for the services of a geologist, the public department cannot attempt to out-bid its rival. Nevertheless there is a happy mean to which, so far as we are aware, none of our Departments of Mines have as yet attained. There was an exodus of geologists from Ottawa two years ago; there are signs that a similar exodus, more complete though on a smaller scale, will take place from Toronto unless the salaries of the geologists employed there are raised to approach more nearly those obtainable in private employ. The Ontario Department of Mines parts with Mr. Knight with regret; it cannot afford to lose one more of its geological staff.

The danger signal is in sight. It is incumbent upon those steering the ship of State in Toronto to see that steps are taken immediately to protect the public interest.

OPERATIONS RESUMED AT SYDNEY

The colliery workers in the Sydney field are being re-employed as rapidly as places can be found for them to work. In some cases water and falls of ground have prevented places being opened to the miners; but such occurrences have been much less frequent than could have been expected after the prolonged shut-down. So far as is known publicly, there has been no discrimination against the bulk of the

strikers in re-employing the force of men; but all have been required to sign the check-off anew — that is, to join the re-organized District 26 of the United Mine Workers of America. This formal recognition of the authority of the international union includes, of course, adherence to the union tenets, among them the necessity for living up to agreements with the Company. The collieries are now fully manned, and we can look forward to a period of undisturbed prosperity in and about Sydney.

An incident in Sydney last week indicates the wisdom of having troops and provincial police on the ground during the period of disturbance. Explosive charges were put off over two spots on the water main that supplies the steel works, cutting off the supply completely for a day. This spirit of sabotage has long been in the air at Sydney, and, though it has infected actively only a small minority of the workmen in mine and mill, still the hare-brained escapades of these few might have had very serious consequences to life and property had not the law been represented by an armed force of preponderating proportions. The troops and provincial police are still on guard on behalf of law and order, and will remain so until the local civil authorities consider the danger of serious disturbance is past. Though the bulk of the miners and mill workers are once more "on the job," there is still a band of disaffected and disgruntled Socialists and Communists at large whose presence is a menace to the community. The British custom does not permit these disturbers of the peace to be rounded up and removed or jailed, as is the custom in other lands. It depends virtually upon the citizens of Sydney and the colliery towns and villages to meet the case themselves.

In general, the steel and coal strikes have resulted fortunately. The grievances of the steel workers, some of which are well founded and require adjustment, could not be met while good and bad were intermingled. There will be now an opportunity for the Company to consider these claims calmly and judicially, and we are confident that justice will be done. The colliery workers are at last rid of the small Communist minority that has led them by the nose during recent years. In this case too we can expect from now on a more friendly mutual relationship between employers and employees. From the indications we judge that a period of unexampled prosperity is ahead for Nova Scotia's coal and steel industries, based upon sound business and engineering management as well as upon a better mutual understanding between company and operatives than has existed for many a long year.

While Germany continues to preserve her virtual monopoly of the world's supply of potash, the discovery of similar beds in other parts of the world where rock salt is found is not improbable. Exploration is being conducted in Spain in beds of salt containing commercial, though erratic, values in potash. Borings throughout the United States are now being examined systematically where they pass through salt beds in order to test their potash content. The Malagash salt deposits on the Malagash peninsula on Northumberland Strait, Nova Scotia, contained in parts an appreciable amount of potash, but not sufficient to warrant an attempt to recover it. Messrs. Chambers and MacKay, who are operating the Malagash salt deposit, have taken steps to explore for salt in Hants County, on the south side of Minas Basin. Two boreholes put down at Cheverie encountered strong brines at depths of 1,400 and 1,870 feet. It is possible that the contemplated exploration of Messrs. Chambers and MacKay will disclose salt beds at a lesser depth, as in their Malagash beds. The new salt industry of Nova Scotia is in good hands, and will be developed vigorously.

Constantly there are announced in the technical press new developments in electro-chemistry and electro-metallurgy. On another page we print a notice of such a plant in Italy, making ammonia and nitric acid from air and water. A somewhat similar plant is being constructed in England by Brunner, Mond & Co., to make ammonium nitrate. These developments augur well for Canada, with her abundance of water-power. The huge power development now in progress at the Grande Décharge of Lake St. John, where it empties into the Saguenay River two hundred miles north of Quebec, must have some such outlet for its energy. Those who are behind the enterprise have made as yet no announcement of their purpose in this regard. We can conclude confidently, however, that the use of the tremendous amount of electric power that will be available there within four or five years rests upon commercially feasible electro-chemical or electro-metallurgical processes.

THE EFFICIENCY EXPERT

A Human Protest

He doesn't like the lay-out of the plant;
He disapproves, in manner arrogant,
The mining methods utilized below;
He hints that they are obsolete and slow.
In everything we try to do, indeed,
He signifies that we have gone to seed.
Efficiency's his battle-cry,—that word
By ordinary mortals deep abhorred.
Efficiency, as reckoned by *per centum*,
We'll let him have—do nothing to prevent him
From being most abnormally efficient,
Or posing as unhumanly omniscient.
But, by the gods! (we hope he'll take the tip)
His talk afflicts us with the purple pip!
So, Mr. Expert, pray abate your ardour,
Life's hard enough, don't try to make it harder!

J. C. M.

CHARLES McCREA

The recent change of government in Toronto has brought with it the assurance that the mineral industry will receive more consideration from the Ontario provincial administration than has been the case in the past. The new Premier was formerly Minister of Mines, and the knowledge gained in that position will give him a distinct advantage, as compared with former premiers, in dealing with mining matters. The present Minister of Mines, Honourable Charles McCrea, brings to his task the aid of a legal training and of over twenty years of residence and practice in Canada's leading mining camp, — Sudbury. He has represented the Sudbury district continuously in the

Hon. CHARLES McCREA
Minister of Mines for Ontario

Provincial Legislature since 1911, when he first stood for election, and on the floor of the House has always been the champion of the mining industry.

Mr. McCrea was born in Springtown, near Renfrew, Ontario, in 1877, and was brought up in the town of Renfrew. He studied law at Osgoode Hall and in the office of Hon. T. W. McGarry of Renfrew, ex-Provincial Treasurer of Ontario. In 1901 he was called to the Ontario Bar, and commenced practice in Sudbury, where he is now senior partner in the firm, McCrea & Valin. In 1921 he was created King's Councillor. Last month he was appointed Minister of Mines in the new Conservative government under the leadership of Hon. G. Howard Ferguson.

During his long residence in Sudbury, Mr. McCrea has of necessity gained an intimate knowledge of the mining industry, which permeates the whole life of the town and creates the larger part of its business, both legal and otherwise. That his interest in the mining industry is also from choice is demonstrated by his record of twelve years in Parliament. He has always taken a responsible part in the discussions relating to mining, and his obvious personal acquaintanceship with the subjects of discussion, which is a rarity in Parliament when mining is the subject, has given his statements and his conclusions authority and distinction.

Mr. McCrea has at his back a staff in the Department of Mines whose experience and ability are notable, not only throughout Canada, but wherever the mining industry of Ontario is known. This staff, old in experience, and with the accumulated wisdom of a long succession of political administrations, dating back to the beginning of the mining camp in which Mr. McCrea's personal interests are mainly centred, is the best possible asset to any Minister of the Crown in the discharge of his public duties.

Mr. McCrea is fortunate. He assumes public office not only with this Department behind him, but at a time, when the mining industry of the province is experiencing the greatest boom in its history. The responsibilities of the Minister of Mines are correspondingly great; and the *Canadian Mining Journal* is confident that Mr. McCrea will discharge these responsibilities in such fashion as will give him a notable place in the annals of mining in his native province.

SYNTHETIC AMMONIA

A plant has been established at Novara in Italy to make synthetic ammonia and nitric acid by the Fauser process. Hydrogen produced by the electrolysis of water, and nitrogen obtained as a by-product, to be explained later, are mixed and compressed to 300 atmospheres and when sufficiently hot, combine to form ammonia. External heat is required to start the reaction, but thereafter the heat of the reaction is sufficient. The ammonia is oxidized to nitric acid by the process of Frank and Caro, using oxygen from the air. The residual gas from this reaction is the pure nitrogen mentioned above. The plant has some ingenious devices conducive to economy, and there is every prospect of its being commercially successful.

PROSPECTING FOR SALT

A license to prospect for salt in Hants County, Nova Scotia, has been taken out by Messrs. Chambers and McKay, of New Glasgow, who are operating the Malagash salt deposits. The license covers an area of 35 square miles. Prospecting in this district will be watched with considerable interest, as salt has been discovered near Falmouth, across Minas Basin from Cheverie.

The Oil Engine for Mine Use

I.—General Characteristics, and Rating

(The power problem is ever before the mining man o an increasingly large extent the use of oil engines ffers either a partial or a complete solution of the roblem. The oil engine is a comparatively new source f power to the mining engineer, and he is not as yet oroughly acquainted with its characteristics. There re in circulation also a number of false notions about il engines, their uses and their capabilities. With a iew to presenting for the use of Canadian miners au horitative oil engine data, the *Canadian Mining Journal* as arranged for a series of short articles from one f the world's principal makers, who has now over a illion horsepower of these engines in use. Though he data and ideas presented are of general utility, the eculiar requirements of the miner and conditions in anadian mining camps have been kept in view. The irst of these articles follows. — Editor.)

Power. — The user is interested in the useful power hat the engine will give out over fairly long periods. This is less than the overload power that can be given n trial conditions for short periods. It is, therefore. ecessary to ensure that the engine be of ample size or the duty required, as it is manifestly unfair to com pare the conservative rating of one make with the ex treme temporary output of another. Most makers of epute state the maximum power they recommend for ontinuous running, which allows a margin under the maximum output possible.

For small engines the brake horse power, or the power actually available for doing useful work, is quoted, so no confusion is likely to arise by quotation of indicated horse power, to which reference will be made later; but it is just as well always to specify brake horse power (B.H.P.) in enquiries. Shaft horse power (S.H.P.) may be regarded as having the same practical meaning.

Height above sea level and temperature affect the power available from the ordinary engine. The power quoted by the maker will be that available at about sea level (say up to 330 feet above sea level) and at normal temperatures (say up to 75 degrees Fahrenheit). It is customary to allow a reduction of at least 1% in the power for each 5 degrees Fah. rise in temperature above 75 degrees Fah., and for each 330 feet above 330 feet in elevation, or 3% for each 1,000 feet. The reason is that at high temperatures and altitudes the air becomes attenuated or less dense, and there is less weight of air in the cylinder to burn the fuel.

Fuel. — The power quoted is usually based on fuel oil of average quality, say not over 0.9 specific gravity, and 18,000 British Thermal Units per pound. The majority of fuel oils come within this description, but if any specially thick or poor fuel oil has to be used it is necessary to state this fact when enquiring. Clean fuels obviously lead to more comfortable running, and less frequent cleaning, than do coarser fuels, and it is often more economical in the long run to use more expensive fuel than the cheapest.

A high viscosity in itself is not necessarily a great difficulty with fuel, as by warming it can be made sufficiently liquid for use. It is as well, however, when using viscous fuel to run for a short time before stop ping on a more liquid fuel that will not solidify in the pipes and pumps and thus make starting difficult.

High viscosity fuels are more apt to hold water and dirt in suspension.

Asphalt is the most difficult constituent in some fuels, as a portion is apt to coke and to form deposits and grit in the engine. Sulphur in the fuel does not appear to cause trouble in its combustion as the gas passes away at too high a temperature to cause corrosion. On cooling down after stopping, acid is apt to form, while exhaust fumes in the air will cause trouble in air compressors. Makers of engines are generally prepared to advise as to the fuels suitable for their engines.

Cycle. — Two-stroke engines have their cylinder covers, liners and pistons subjected to more heat stress than four stroke engines, as there are twice as many impulses for the same number of revolutions. In large engines heat stresses become important, and on this account a lower output per impulse is required with a two-stroke engine than with a four-stroke, if one assumes the same degree of durability for both. For engines of the semi-Diesel type the rating is usually very low, and this point of durability is automatically met; but in large engines care must be taken in accepting the claims made for the two-stroke engine, which are often exaggerated. The main point in a two-stroke semi-Diesel engine of reliable make is its extreme simplicity, which offsets the advantages in other directions that may be claimed for a four-stroke engine in the same field.

Rating of Engine. — The power of an engine can be measured by taking indicator diagrams, as is done with a reciprocating steam engine, or by measuring by a brake or dynamometer the actual rate of work delivered at the coupling. The former gives the indicated horse power (I.H.P.), the latter the brake horse power (B.H.P.), the latter often known as shaft horse power or useful or effective horse power. The ratio $\frac{\text{B.H.P.}}{\text{I.H.P.}}$ is the mechanical efficiency of the engine (E), or

$$E. = \frac{\text{B.H.P.}}{\text{I.H.P.}}$$

Knowing two of these three values, the third can be at once found. E may vary from below 70 to well over 80, according to the type and size of engine; so the I.H.P. is obviously a poor guide to the useful power (B.H.P.) unless E is known.

Mean Pressure. — From the indicator diagram we can calculate the mean indicated pressure (i.m.p.) and by using the formula below, the I.H.P. is derived. Conversely the i.m.p. can be calculated, given the I.H.P. and the engine particulars.

$$\text{I.H.P.} = \frac{\text{i.m.p.} \times 1 \times a \times n}{33000}$$

(for a two-stroke single acting engine)

$$\text{or} = \frac{\text{i.m.p.} \times 1 \times a \times n}{2 \times 33000}$$

(for a four-stroke single acting engine)

where 1 = length of stroke of engine in **feet.**
a = area of piston in square inches.
n = number of revolutions per minute.

i.m.p. = mean indicated pressure in lbs. per square inch.

The mean indicated pressure is a guide as to the heat effect per impulse.

Corresponding to this is the brake mean pressure

$$\text{B.H.P.} = \frac{\text{b.m.p.} \times 1 \times \text{a} \times \text{n.}}{33{,}000}$$

(for a two-stroke single acting engine).

$$\text{or} = \frac{\text{b.m.p.} \times 1 \times \text{a} \times \text{n.}}{2 \times 33000}$$

(for a four-stroke single acting engine)

The ratio between i.m.p. and b.m.p. is obviously the same as between I.H.P. and B.H.P.

The b.m.p. is useful as a guide to the pressure rating of engines of the same type and speed.

The stroke multiplied by twice the number of revolutions, or $1 \times 2n$ gives the piston speed, which is a rough guide as to speed rating of the engine.

THE GEOPHONE*

The geophone is a sound-ranging instrument invented by the French during the war. The form of the instrument was developed by the U. S. Army Engineers and the U. S. Bureau of Standards. Later the sensitiveness of the instrument was increased by engineers of the U. S. Bureau of Mines. The instrument is, in principle, a seismograph and is entirely mechanical in its action. The geophone consists of a flat iron ring about 3½ inches in diameter and ½ inch in thickness, in the center of which is suspended a lead weight fastened with a single bolt through two metal discs, or diaphragms; one of these diaphragms covers the top, the other the bottom of the iron ring. There are two brass cap pieces, the top one having an opening in the center to which is fastened a rubber tube leading to a stethoscopic earpiece.

If the instrument is placed firmly upon the ground and there is any pounding or digging in the vicinity, the case of the instrument will vibrate with the earth. The lead weight, because of its mass, will, however, remain comparatively motionless, since it is suspended between the elastic diaphragms. There is thus produced a relative motion between the diaphragms and the case. This motion alternately compresses and rarefies the air in the spaces between the cap pieces and the diaphragms. The air waves thus set up within the instrument are then transmitted to the observer's ears by means of the rubber tubing and the earpieces. The small enclosed air-space in the bottom of the instrument, between case and diaphragm, serves to dampen the vibrations of the diaphragms. It is customary to use the geophones in pairs, connecting one instrument to each ear. The direction of a sound from an observer can in this way be determined with considerable accuracy on the binaural principle of direction determination, as has already been outlined in Research Narratives No. 18 and No. 51.

The diaphragms in the original instruments were mica. It has been shown, however, that metal diaphragms are more sensitive and more durable. A nickel diaphragm .025 inch in thickness is perhaps best. The thickness of the diaphragms is apparently limited by the ability of the enclosed bottom air pocket to prevent undue vibration.

To give some idea of the sensitiveness of the instrument, it may be said that under suitable conditions sledge pounding has been detected over three thousand feet through solid rock in a western metal mine, that the same pounding has been detected two thousand or more feet through coal, five hundred feet through mine "cover," and about three hundred feet through clay. External noises, such as those caused by light winds, or machinery running nearby, greatly interferes with the successful operation of the instrument. The characteristics of the sounds are transmitted very accurately through the geophone. This means that one can easily judge the nature of the machine or instrument making the sound. Talking can be heard through an ordinary 50-foot coal pillar with about the clearness of the old-fashioned phonograph.

While the geophone was first used to detect the underground mining operations of the Germans, it has been successfully applied to many peace-time purposes. The instruments may frequently be of value in locating and rescuing miners who have been entombed in a mine disaster. They have also been used successfully in establishing roughly the relative positions of approaching tunnel headings, and may thus serve to prevent accidents incident to blasting through unexpectedly. Then can frequently be employed in determining the drift of churn-drill holes, and experiments with diamond drilling seem to indicate that under certain conditions they would serve the same purpose with such drills. While it might not always be possible to follow the drill from the surface, it is certain that if the hole were being put down ahead of accessible workings the geophones might be useful. Under exceptional conditions they have served in locating mine fire areas. Usually the sounds from such a fire are too weak to be transmitted any great distance. Most satisfactory results have been obtained in locating water-pipe leaks, and one mining company reports success in locating leaks in compressed air lines buried along their entries. They report, however, that they were unable to detect the very smallest leaks.

PERSONAL AND GENERAL

Mr. J. U. MacEwan, recently chemist at the lead smelter of the Kingdon Mining and Smelting Co. at Galetta, Ontario, is now superintendent of the smelter. He succeeds Mr. F. S. Warren, who has returned to the United States to take a position with the Evans Lead Co. in Forestia, Ohio. Mr. MacEwan's friends will be interested to know that he is no longer a bachelor.

Professor S. N. Graham left last week for a three weeks trip in northwestern Quebec.

Mr. Andrew G. Larsen of Spokane, Washington, has returned from Stewart, B. C., after inspecting a number of claims in the Portland Canal district.

Mr. E. Mc G. Quirk, of Montreal, has been appointed Chairman of the Conciliation Board that is considering the demands of the Porcupine miners for higher wages.

Mr. Thos. Riggs, Vice-President of Continental Mines, has been visiting the company's properties in Cobalt and Kirkland Lake.

Mr. Robt. A. Bryce, of Toronto, has returned from Porcupine and Cobalt

Mr. M. C. H. Little has returned to Canada from Italy.

* Research Narrative No. 61 Engineering Foundation, By Alan Leighton, Physicist, Bureau of Mines.

Rubber Lined Ball Mills

A new Use for Rubber — Ball Mills with Rubber Lining Outwear Steel — Construction and Production Advantages

(From The India Rubber World)

Two Types of Ball Mills

Ball mills are extensively used in the mining industry for breaking up ores. There are two types of mills in common use; the principal one is the cylindrical ball mill that ranges in diameter from 5 to 6 feet and from 16 to 22 feet in length. These mills are practically steel shells that vary in thickness from ⅝ to ¾ of an inch and are provided with flanges at each end to which the heads are fastened that carry the bearings upon which the shell revolves. The other type is known as the conical mill, which is comparatively short and in diameter ranges from 10 to 12 feet. The body of this mill is usually constructed of grey iron or steel castings.

Steel Protective Linings

Both types of mills are fitted with inside linings which may be removed when worn. Then object of these linings is to protect the main shell against wear. In order to resist the abrasive action of the ore, these linings are chrome or manganese steel castings that vary from 2 to 3 inches in thickness and are therefore quite heavy. This means considerable cost for material and also for power required to drive the mill. The principal objection to the use of steel linings is due to the fact that they gradually wear out the shell due to the constant friction between the lining and shell, aggravated by small particles of the reduced ore. The cost of a perfect fit between the heavy castings of the lining and the shell, is prohibitive. This is clearly true of both the cylindrical and conical types of ball mills. Indeed, this condition is so serious that the tendency is toward making cast steel shells of 1½ inches in thickness and over in order to insure long life despite increased cost, weight, and greater power consumed.

In comparatively small installations there are 4 to 6 ball mills in operation, while larger plants have from 10 to 20 and sometimes 30 mills or more. The shut-down for replacing steel linings in a mill requires two days at least. In the case of a mill handing 100 tons per day of a recoverable mineral value of $10 per ton, a production loss of $2,000 per mill is the result of this loss of two days' time. As a rule linings are replaced three times in two years and therefore the production loss per mill per year amounts to $3,000.

Briefly stated the objections to the use of metal linings are as follows: Cost, weight, increased driving power, abrasive wear on the shell, shut-downs and cost for replacement of parts.

Advantages of Rubber Linings

Experimental ball mills are now in operation wherein sheets of rubber are being used in the place of the ordinary steel linings. These rubber sheets are approximately 7 to 8 feet long and about 16 inches wide and ⅝ of an inch thick. These rubber sheets are made in convenient size and afterwards cut to fit the inside dimensions of the mills.

The advantages of using rubber sheets in ball-mill construction are as follows:

1. The lining weight is greatly reduced, hence less power is required for driving the mill. On the basis of power per ton of finished product the comparison between steel and rubber is in the ratio of about 17 to 13 or a saving of nearly 24 per cent. There is less load on the bearings, which last longer.

2. Due to moisture in the ore and introduced with it, the inside of the shell is soon covered with rust, to which the rubber lining freezes, holding it firmly in place and eliminating friction between the lining and shell.

3. The advantage under paragraph 2 prolongs the life of the shell.

4. The initial as well as the up-keep costs are greatly reduced. Chrome or manganese liners 2 to 3 inches thick cost about 11½ cents per pound. Rubber will cost from 55 to 70 cents per pound. The difference in weight will all be in favor of rubber.

The advantages in favor of rubber from the production standpoint are:

1. The capacity of tube or ball mill is in proportion to its diameter. The substitution therefore of metal linings 2 to 3 inches thick by a rubber lining only ⅝ inch thick materially increases the output.

2. In a metal-lined mill the ore as well as the balls slide readily over the inside surface; not so in a rubber-lined mill.

Observations have shown that in a rubber-lined mill the working zone is materially increased and the inert zone reduced. This is assumed to be due to the fact that the ore and ball mass, pressing against the rubber, is prevented from sliding and does useful work.

3. Experience has shown that a rubber lining averages 13 months of usefulness before it has to be replaced, as compared with 8 months for a steel lining.

4. The relining of a mill with rubber is a very simple operation. A mill can be relined in one-half day or in one-quarter the time consumed when using steel linings. Due to the limited weight of the rubber strips they are readily removed and the new ones rolled up are introduced through the manhole into the mill. The cost of labor in relining is thus cut down.

5. More important than the last consideration, however, is the fact that the rubber-lined mill at the time of relining is kept out of production only one-half day as against two days for a steel-lined mill, steady production being of prime importance.

Rubber Linings in Operation

The use of rubber for mill linings is at present being demonstrated at the mills of a prominent mining company, where a mill completely lined with rubber ⅝ of an inch in thickness is in operation. The mill has been in uninterrupted operation for 3 months, and no appreciable wear of the lining is noticed. The ore handled is of medium abrasive quality. The process has evidently passed the experimental stage and seems established. At present a mill is being fitted out for coarser work, taking ore at 2 inches diameter and reducing with large balls to ½ inch and finer.

Patent applications covering this invention have been made in the United States, Canada and other countries.

Steady shipments of Swedish iron ore are being made to the eastern seaboard of the United States. West bound freight rates favour this traffic.

Mining and Advertising*

To Create New Markets and Stimulate Old Ones is Part of the Miner's Problem

By JAMES H. COLLINS

Some years ago a wonderful deposit of nickel was found in the Sudbury district of Ontario — a bonanza for Canada, because it gave her something to sell the United States that is not produced in our own borders. Yet if Canada found another such nickel deposit tomorrow, it would be valueless; for Sudbury itself can produce more nickel than the whole world needs. For the same reason, an antimony mine would have no market value.

Some metals are in such good demand that their mining is steadily profitable. The world's supply of platinum is never adequate for its needs. Tin is absorbed about as fast as it is mined. But they are very few, these minerals with an adequate market. Generally, the miner can produce far more of a given metal or non-metallic mineral than the world wants. Among the staple metals, those needing more consumption are gold, silver, lead, zinc and copper. Among the rare metals, platinum is almost the only one with a hungry market. Cobalt, vanadium, magnesium, tellurium, cadmium, bismuth, uranium — these all have unsolved marketing problems, the possible production far exceeding demand.

Some "Rare" Metals a "Nuisance"

The public calls them "rare," but to the miner they are "nuisance" metals, or have been in the past, getting in the way when he extracts marketable minerals.

Platinum was a "nuisance" metal when the Spaniards first found it mixed with gold in the West Indies, and threw it aside as valueless. Today it is more costly than gold, and estimated on that account in jewelry. It is also a highly useful metal, making laboratory utensils with a very high melting point, not affected by most chemicals, and also valuable in dentistry, as a catalytic agent and for electrical purposes such as contact and ignition points.

Tungsten was a "nuisance" metal twenty-five years ago, and miners complained bitterly because it had to be taken out with silver and thrown on the dump. When it was adapted to incandescent lamp filaments it became more valuable than silver.

What Was Done With One "Nuisance" Metal

Canada has an outstanding "nuisance" metal in cobalt, which is found in Canadian silver ores to such a degree that 175,000 tons of silver ore contain 7,000 tons of cobalt. Apart from its limited use as a blue coloring substance there is little demand, and thousands of tons have accumulated as residue at the smelters. But the possibilities in such metals were shown by Elwood Haynes' invention and advertising of "Stellite," an alloy of cobalt with another rare metal, chromium, which contains no iron, yet as a machine-tool metal will work at speeds that burn up the best tool steel, and take cuts that would crumble steel. Laboratory uses have been found which may ultimately be commercialized to put the cobalt market on a tonnage basis. Small percentages in pure iron make non-corrosive alloys which might find uses in roofing and sheet metal. Cobalt electrically plated on steel and brass gives a more adhesive coating and a better appearance than nickel, which it resembles. More costly than the latter, it can be deposited several times as fast and is less easily corroded. It is also used to some extent in coinage and German silver.

The Advent of Vanadium

Few advertising men realize how broad this field is, or how consumer interest may be needed tomorrow for the development of new uses discovered in the laboratory.

Twenty-five years ago few people outside the laboratories knew that there was such a metal as vanadium. Hiorns' comprehensive treatise on metals and alloys, dated 1901, makes no reference to it whatever. Del Rio isolated it from a Mexican lead ore in 1801, but his discovery was discredited until Sefström confirmed it thirty years later. In 1900, some Pittsburgh steel men, having vanadium deposits in Peru, undertook to create a demand for this unknown product. As a laboratory proposition it had been found valuable in imparting anti-fatigue properties to steel, but the steel men had not taken it up. The Flannerys had some first-rate technical articles written by metallurgists and engineers, showing the superiority of vanadium steel. Booklets were also prepared, but no periodical advertising done, chiefly because the promoters didn't know how to go about such a campaign. In the course of their promotion work, they interested Henry Ford, who adopted vanadium steel for his cars. That gave it the greatest single impetus, because Ford told the public about the advantages of this alloy steel in wear and lightness. Another novelty that brought wide publicity because it was something appealing to the popular imagination was a "vanadium shovel," having wearing properties and lightness due to vanadium steel. Today the market for vanadium steel is being still further increased by the advertising of several tool and machinery manufacturers who use it in their products.

The Copper Problem

Even the commonest metals have undeveloped advertising and marketing possibilities.

Take the best advertised metal of the moment — copper. The public has not only responded to publicity pointing out the durability of copper, but manifested widespread interest in copper advertising as information. But the use of the red metal for roofing, plumbing and hardware is just a beginning in the possibilities.

Only yesterday, for example, copper was thought to be "poisonous" to iron, and even Government contracts specified that iron should contain not more than a certain percentage of copper. Metallurgists were set making tests. They demonstrated that, far from being injurious, copper improved iron and steel, making them resistant to corrosion. As an outcome

* From "Printers' Ink," June 14th, 1923.

of advertising in technical journals, this old superstition has been scotched and Government contracts now specify certain percentages of copper in iron and steel.

A New Demand For Copper

A growing new demand for copper is found in the use of copper sulphate for purifying city water. A very small amount of this chemical, about two pounds per million gallons, added before filtration, kills vegetable pollution and removes unpleasant flavors. Copper shingles, coper kettles and other articles are also used, now advertised in large space. Copper sulphate is being used in building a new type of road, three per cent added to asphalt protecting the latter against "running" in hot weather. Copper oleate is used for impregnated fish nets so they will not be affected by marine pests, replacing tar which has always been used for that purpose. Copper alloyed with steel, the American Sheet & Tin Plate Company advertises, adds to the permanence of black and galvanized and roofing tin plates.

It may be well be that later on, when the merits of copper metal have been impressed through advertising, the research association will turn to the many brasses made by alloying copper with other metals. The public knows the bright golden brass of the kitchen faucet, made of copper and zinc, but it does not know the many white and red brasses in which nickel, tin, lead, iron, gold and other metals are also used for jewelry, silverware and other purposes. "German silver" is really a white brass made of copper and nickel. And so with the bronzes, which are copper-tin alloys to which other metals are added for ornamental and utilitarian purposes — "gun-metal" is a familiar example known to everybody.

$100,000 a Year to Advertise Zinc

Zinc is another every day metal that needs advertising—needs it so badly, in fact, that a campaign was started several years ago by the American Zinc Institute, but halted by the business depresssion. The advertising was resumed recently and in May of this year the institute passed a resolution "to perfect and execute a plan to raise and expend all of the moneys so raised in a sum not exceeding $100,000 for the purpose of conducting a national advertising campaign for zinc products for the coming year." Like copper, it goes on the toboggan slide in hard times, falling below the cost of production, and even in normal times could be mined in much larger quantities than are needed. Unlike copper, which we export, there is vigorous foreign zinc competition in our metal markets.

Zinc needs advertising even more than copper because it is handicapped by popular prejudice. People generally know the virtues of copper without being told — the only question in the public mind is that of cost, with which advertising is dealing. But one of the principal uses of zinc is for galvanizing iron and steel. Because the latter are perishable and eventually rust, the public has come to believe that zinc is also perishable when it is really a most durable metal when pure, taking on a firmly adherent coat of zinc suboxide that protects it from the atmosphere. It has also been handicapped by such nicknames as "spelter," a mediaeval Low German term for pewter and solder, now used chiefly in the brass industry for ingot zinc. Still another marketing handicap in this industry was pointed out by Charles M. Schwab who, in speaking to zinc men several years ago, expressed surprise that they had so many business secrets in the way of cost data, the operation of mines and the reduction of the metal. This has undoubtedly saddled the industry with wasteful methods and kept up production costs.

A Way to Increase Sales

One excellent way of selling more zinc, it is said, would be improving the quality of galvanized articles. Another, to encourage the use of pure sheet zinc for cornices, gutters, roofs, eavetroughs and so forth. During the war there was an extensive development of our zinc rolling facilities, the metal being used for lining cartridge boxes and other military purposes, and these facilities are not being employed anywhere near capacity. Great quantities of zinc oxide are used as a filler to improve the resiliency and durability of automobile tires.

The public never thinks of lead and silver as twin metals, but they are to the miner, from both the production and marketing standpoints. A considerable proportion of these metals is extracted from ore that contains both, and according to the state of the market, one is a by-product of the other, sometimes silver paying for the extraction of lead and vice versa. On this basis, a great deal of silver is mined at a profit because lead pays part of the cost where pure silver ore cannot be profitably worked.

Lead and Telephones

In hard times, lead goes on the toboggan slide with copper and zinc. American producers are put under a handicap by imported foreign lead. Indirectly, advertising is constantly creating new lead consumers, for 10 per cent. of our total output is used in the telephone industry as covering for telephone cable — the Western Electric Company purchased 53,000,000 pounds for that purpose in 1921. Another indirect consumer lift is given in the advertising of modern bathrooms and sanitation, for the metal is used for plumbing, water, gas, and fuel pipes. Still another important new use, created largely through the advertising of handy packages for dentifrices and toilet goods, is the collapsible tube, made sometimes of pure tin, but sometimes alloyed with lead. The metal is also used for solder, type metal, weights, sinkers, storage batteries, bullets, shot and lining for acid-proof tanks. The National Lead Company is also spreading a better knowledge of lead in a special campaign.

Silver a Cheap Metal

Silver is not a precious metal to the miner. By and large, it probably sells at a closer margin than steel. The North American continent is the greatest producer, and Asia the largest consumer in bullion and coin. The moving picture industry has created an important new outlet in recent years — leading film manufacturers are said to use three tons weekly, or one-twelfth the domestic output. Considerable quantities are used for still photography, mirrors, silver-plating, indelible ink and like purposes. But the most promising market for this metal, say investigators, is in the substitution of sterling silver for plated ware — that is, substituting silver for its own substitutes. The cheapness of silver until recently was not properly demonstrated to the public. The International Silver Company is advertising to dispel this misconception. An interesting argument formerly used by Tiffany's clerks — it

may still be used today—was putting sterling silver articles like spoons on the scales and figuring their close approximation to the value of silver bullion per ounce. Generally, solid silver is much better value than plated ware, manufacturers maintain, partly by reason of the higher value of the raw material, and partly because silver, being softer than the alloys from which plated ware is stamped, can be much more easily worked.

Gold is another problem to the miner. It is sold at an unvarying price all over the world but production costs are not "pegged," and since the war they have been higher than the value of gold in so many cases that production is not profitable. Besides being the basis of currency, gold has many industrial uses, quantities being worked up into jewelry, beaten into gold leaf for gilding, signs, the branding of pencils, hat bands and other goods, and it is also used in dentistry. But advertising to increase these outlets will not increase the price, so of all metals gold presents the knottiest marketing problem.

Studies of Marketing

Almost the first attention given to marketing metals and minerals is a series of articles in *Engineering & Mining Journal-Press,* each devoted to a single product. Some of these articles have been written by engineers, others by metal dealers, and still others by Government experts, and they will appear ultimately in book form. They deal largely with the commercial channels through which metals pass from the mine or smelter to purchasers who buy them as raw material. The consumer and advertising angles of marketing are occasionally touched upon, but only suggestively.

Many of these products the advertising man will never have heard of, much less their marketing problems.

There are selenium, tellurium and cadmium, three sad cases of metals in abundant supply with negligible consumption. They are used to some extent in medicine and for tinting or decolorizing glass. Magnesium is a lustrous silver-white metal, a light-weight relative of aluminum and beryllium, of which small quantities are used in flashlights and fireworks, but with nothing like the demand that is needed to make it a sound mining proposition. Of tellurium only a few hundred pounds are used yearly, for coloring glass, making dyes and medicine staining silver, and as an ingredient in re-resistance alloys. But new possibilities are suggested by a recent discovery that it makes an anti-knock and carbon-eliminating compound for automobile use.

A story told of palladium, one of these rare metals, reveals a market obstacle of a peculiar kind. Palladium is used to a limited extent in chronometers, watches, surgical instruments and other delicate apparatus. Technologists suggested that $1,000 might be spent profitably to develop other uses, but the principal producers of palladium, according to the story, said that while they didn't mind spending the money, they would do nothing to lower the price of palladium by increasing consumption.

What Advertising Did for Aluminum

When the advertising man begins talking to the miner, let him bear in mind the astounding development of the first advertised metal—aluminium. When he was a kid, glowing predictions about what this wonderful light metal would do constantly appeared in the press. It was well known by hearsay to most people before they ever saw a specimen. The first marketing of aluminum was in the form of disc like coins, sold for a nickle apiece . With cheap methods of extraction, aluminum has gained a reputation as the "heavy duty metal," replacing other metals in automobile parts, being widely used in the form of alloys, and popular with the housewife in advertised aluminum utensils. Despite competition of foreign aluminum, it is practically the only non-ferrous metal that shows considerable increase over pre-war figures of production and consumption. Copper, zinc and tin have suffered decreases from 25 to 60 per cent, but aluminum holds its own, and unquestionably the advertising of aluminum utensils to the public, and aluminum alloys and parts in technical publications, together with its original appeal as a novelty, has done the business.

Research and the Advertising Man

One chap the advertising man must keep close to in this new and almost unexplored field of marketing. That is the technical man who seeks new uses for the neglected metals and minerals. In the laboratory of the metallurgist and chemist, and the office of the engineer, promising new uses may be found any day, and consumer or technical advertising will be needed to put them on a commercial basis.

Canada's joy at the discovery of the Sudbury nickel deposit was dampened somewhat by the later discovery that much of the ore contained copper, which was difficult to separate. "Why separate them?" asked Ambrose Monell, a metallurgist, and studying the alloy smelted from the metal as it came from certain parts of the mine, containing nickel, copper and traces of other metals, he found that it was a valuable new alloy in itself. Thus "Monel metal" was originated and patented, with such virtues of its own that with technical exploitation and advertising, it has become an important separate product of the Canadian nickel industry.

So let the advertising man keep close to the metallurgist's elbow, for each, in his own technique, will undoubtedly have marvels to show the other.

INTER-IMPERIAL TRADE

Canadian importers who are desirous of establishing connections with British manufacturers and ascertaining the best sources of supply, should avail themselves of the services rendered by the Information Bureau of the British Overseas Trade Association Ltd., Imperial Buildings, 56, Kingsway, London. All such information is furnished free of charge, the Association having recently been formed to foster trade within the Empire, and the gentlemen who are responsible for the organisation are practical business men with many years experience of buying and selling in the export market.

GYPSUM

During 1922, 3,779,949 tons of gypsum was mined in the United States. Of this approximately 2,500,000 tons was calcined, its value in the various products resulting being $27,000,000. Neat plaster, wall board and stucco were the principal products. In addition 770,725 tons of crude gypsum was sold for $2,443,346.

Canadian Ingersoll-Rand

The Company's History, its Plant and its Products

The Canadian Ingersoll-Rand Company is one of the oldest and best known makers of industrial machinery in Canada. The shops that commenced operations a third of a century ago, when our industrial organization was extremely youthful, have been expanded to a size and complexity in accordance with our present highly organized industrial system. The steady rise of this company to its present position of importance is typical of those substantial corporations that progress and endure almost with the centuries. Thorough workmanship, business morals of the highest order and policies formulated in accordance with the fundamental laws of economics are the solid rocks upon which such a business is built.

Has Grown with the Mining Industry

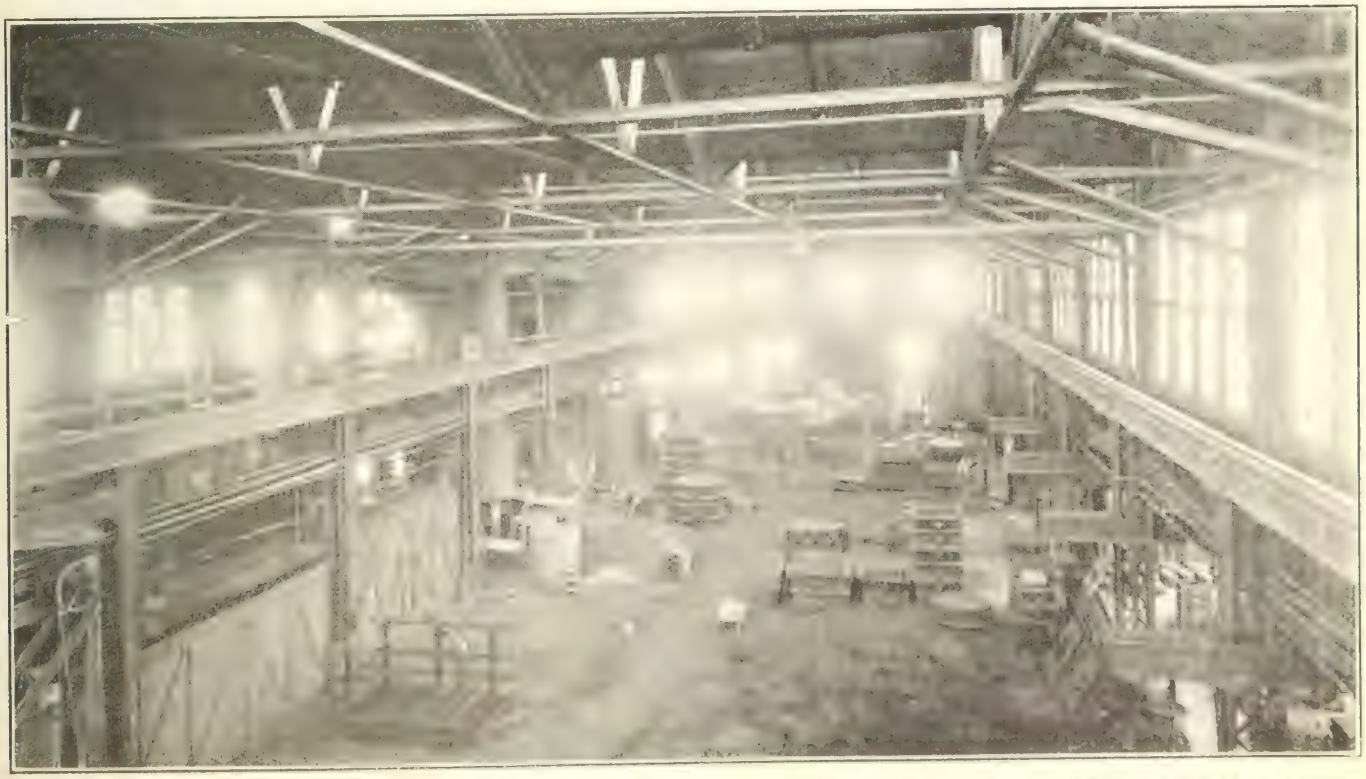
The Canadian Ingersoll-Rand Company, as well as the associated company in the United States, has always been identified closely with the mining industry. In fact the pioneers of the company, Messrs. Rand Sergeant and Ingersoll, each commenced his business by the manufacture of rock drills in New York in 1871. Other mining machinery was added to the output of both companies founded by these men, particular attention being paid to the use of compressed air.

The Canadian enterprise originated in the shops of the Jenckes Machine Company in Sherbrooke, Que. This company had been doing a flourishing machine-shop and foundry business, particularly in connection with the railway construction that was active at that time. During the '80's of the last century the mining industry began to develop rapidly and the Jenckes company arranged with the Rand company of New York to establish in Sherbrooke a factory for the manufacture of mining machinery. This was called the Canadian Rand Drill Company. Rock drills were made in their own little shop, while air compressors were built in the larger Jenckes shops.

Original Companies Merged in 1906

Meantime the Ingersoll Sergeant Co. had established a Canadian branch in Montreal. Their line of mining machinery was made in the shops of the James Cooper Manufacturing Company, under the direction of Mr. Gilman. In 1906 the Ingersoll and Rand companies in the United States were merged, and immediately the Canadian companies followed the same course, Mr. Gilman being put in charge of the combined companies, which position he still holds. Before this amalgamation took place, the original close connection between the Rand and Jenckes plants in Sherbrooke had been broken, so that the Jenckes company took no part in the merger. The new combined company kept the shops of the Rand company in Sherbrooke, which have gradually been expanded to their present important dimensions.

The associated Ingersoll-Rand companies have now seven factories, five of them in the United States and two in Canada. In addition they have agencies and stock-rooms throughout the world wherever the dimensions of the mining industry or other industries using compressed air warrant their attention. In addition there are a number of small assembling and repair shops, as in England and South Africa, for the convenience of those who use their machines.



A view in the foundry, showing the two cupolas and annealing furnaces in the left bay, the casting floor in the centre, and the finishing bay on the right. The raw materials enter by a high-level railway switch to the left, and the products move across the floor, out to the machine shops and into storage, always in the one direction.

Consistent Research Work

The Ingersoll-Rand enterprises were founded upon, and have progressed by means of, industrial research. Their work of investigation began with their first rock drill, long before the term "research" was used; and it continues today, with the aid of the many devices human ingenuity has provided during the last half-century. A visit to the shops in Sherbrooke discloses this practical research work at every turn. Where formerly it was left to the individual initiative of mechanics, foremen or managers, now it is highly organized, not only taking advantage of the ideas and practical skill of men in the shops, but also availing of the services of highly trained designers and mechanical engineers. Thus progress is certain and financial stability is assured.

Research has been required especially since the introduction of the modern high speed, light weight pneumatic tools. These require metals of a grade not dreamed of in former days. The materials of the hammer drill, for instance, must withstand usage that would smash to atoms or pound to a shapeless mass most of the steel used fifteen years ago. This steel is provided by steel manufacturers to specifications made by the machine company, after extended experiments, and then must undergo special treatment in the shops, such as heat treatment, case hardening or annealing, to bring out the special qualities required. Nowhere is a more exact knowledge required of the qualities of alloy steels than in the shops where pneumatic tools, and particularly rock drills, are made.

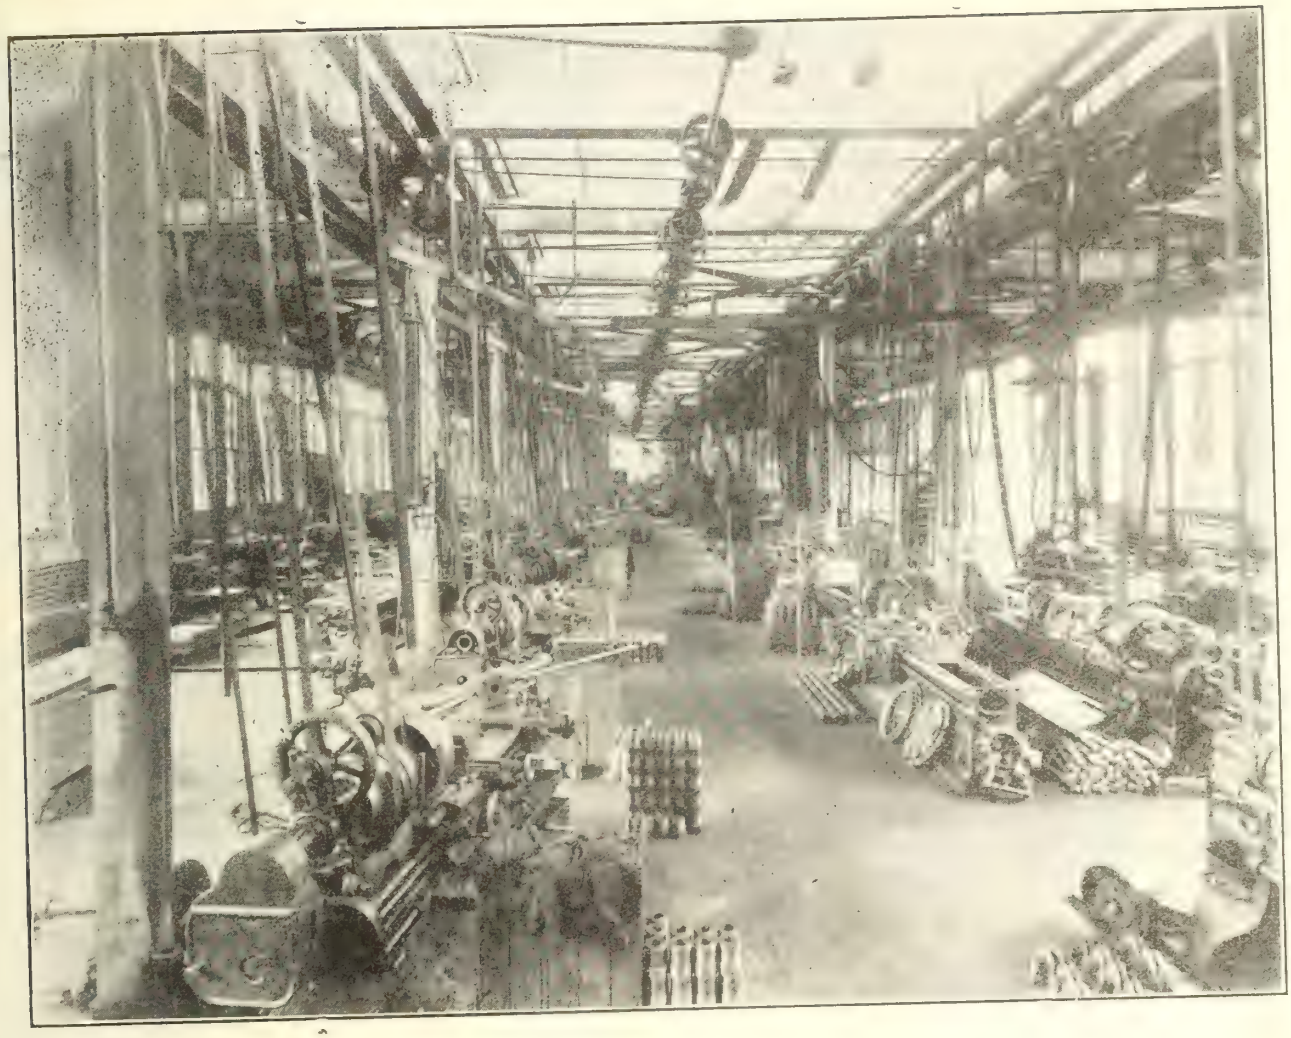
New ideas in design are a most important part of a machinery firm's stock-in-trade. It is gratifying to know that this Canadian company is well aware of the fact and has an adequate and competent staff continuously at work formulating ideas, licking them into shape in the drafting room, building the machines in the shops and then proving or disproving their usefulness by working trials. In this work the firm has the active co-operation of a number of customers, in whose shops or mines some new machine is continuously being tried out in practice.

Though the company has the advantage of a complete *liaison* with the plants in the United States, their practice is not always followed. The smaller Canadian establishment allows of a more rapid change to suit advances in design or improvements in construction.

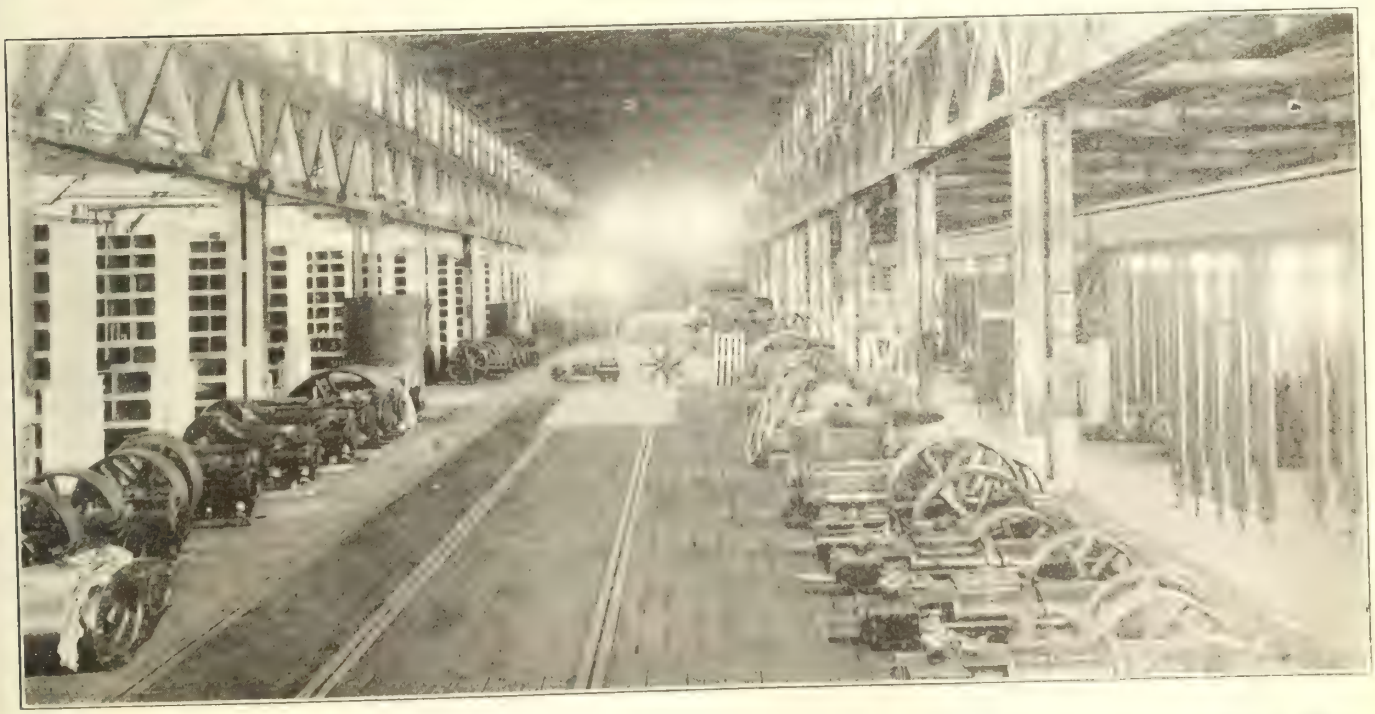
The Sherbrooke Shops

The principal shops of the Canadian Ingersoll-Rand Company are on a site of 23 acres adjacent to Sherbrooke's C. P. R. station. The principal buildings are a foundry, 102 feet by 242 feet; No. 2 shop, where compressors, pumps and hoists are made, 202 feet by 562 feet; No. 3 shop, for the manufacture of coal cutters, Leyner drill sharpeners and the larger types of rock drills; some smaller shops where the smaller hammer drills and pneumatic tools are made; a forge and heat-

No. 2 Shop, where compressors, pumps and hoists are made. This is one of the largest machine shop structures in Canada



No. 3 Shop, in which are made coal cutters, Leyner drill sharpeners and large rock drills



One of the finished store departments at the Rand Plant. A large stock of many of the products is kept on hand for immediate delivery. To the left are shown some of the self-inventoried racks in which are kept spare parts and disassembled small machines.

treatment department; a brick pattern shop, 60 feet by 100 feet, and four pattern storage buildings; and a building 90 feet by 303 feet, formerly No. 1 shop, now used to house the large stock of machines and spare parts that are an integral part of Ingersoll-Rand service.

The factory system used throughout this plant is the system characteristic of this continent. Machines are put through the shops in batches wherever possible, and parts are made exact duplicates of one another, so as to be interchangeable. In fact some of the smaller machines are kept stored piecemeal, in racks, so that complete machines can be assembled at will or, alternatively, they can be used to fill orders for separate parts. The storage system for parts is an ingenious one, providing for automatic and continuous stock-taking, with a result that the stock is seldom either depleted or over-supplied to any appreciable extent. This perpetual inventory has been adopted as a useful device by other firms.

The Jenckes plant, on a separate site on the other side of the town, was taken over during the war time. It is fitted up for making castings, boilers, paper-making machinery and general industrial machinery.

Rock Drills and Coal Cutters

As mentioned above, the original Ingersoll-Rand product was rock drills. The development of the rock drill for fifty years has been largely the result of work by this firm and its coadjutor.

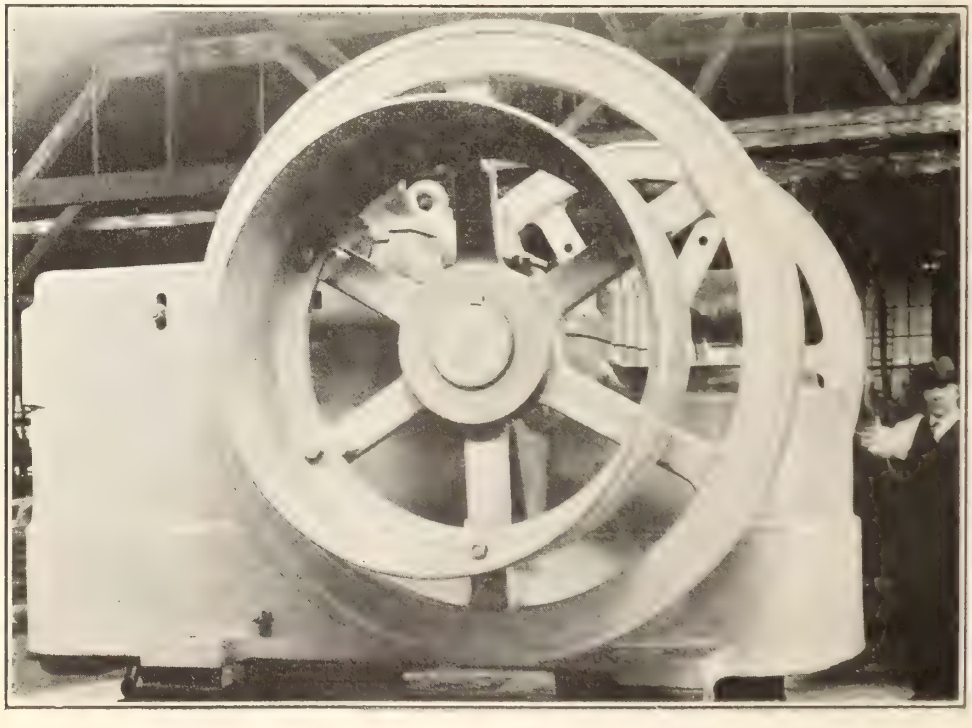
The Canadian shops developed some years ago, and now supply to all quarters of the globe, an outstanding coal mining machine, the "Radialaxe", or coal puncher. A great many of these are used in the collieries of Nova Scotia, and they have been supplied to collieries in most countries with an established coal mining industry.

Testing a hammer drill in a block of Barrie granite for speed and air consumption. This is the last of numerous tests to which all the rock drills are subjected.

Air Compressors

Air compressors are made ranging in size from the huge, high-speed machines built to special order, down to the tiny machine designed to run a single pneumatic tool. An interesting recent development is a portable self-contained unit on wheels or skids, consisting of a gasoline engine and a small compressor designed to supply either one or two full-sized rock drills. Curiously enough, one of the compressors in the plant's modern power house exemplifies the old adage about the shoemaker's children; there is still in use, and likewise in perfect condition, a compressor that was out of date ten years ago. This faithful old servant of the company works alongside larger and more modern types.

A type of air compressor that will appeal particularly to Canadian mine managers is one made for alternative steam and electric drive. This will meet the requirement of numerous mining camps, particularly in Northern Ontario.



A "Circo" jaw crusher, 42" by 36", — one of many built for service in the Quebec asbestos mines.

The Ingersoll-Rand Shop Band. Noon - hour concerts by the "Circo" Band are a feature of the summer months.

Hoists

Hoists are made also in all sizes and for all purposes. During recent years there has been a marked advance in the design of electric hoists. An important new development is now being worked out in the shops at Sherbrooke which will give the electric hoist an even more secure hold on the market.

There are multitudinous other products of these shops, all of them directly connected with or accessory to the use of compressed air. All go to swell the output of a company whose long record gives it a secure place in the annals of Canadian industrial progress, and whose future, based upon faithful service, is found to be in keeping with its past.

BARYTES AND BARIUM PRODUCTS IN 1922

The sales of barytes mined in the United States in 1922 amounted to 155,000 short tons, more than twice as much as in 1921 and about 75 per cent of the average yearly sales for 1916 to 1920. The total value of the domestic barytes sold in 1922 was $1,123,950, an average of $7.25 a ton.

Barytes is a heavy white mineral that enters extensively into modern paint manufacture. An inferior grade of pigments is made from it by grinding it so fine that its powder can be floated on water. A better grade of pigment is made by chemical treatment, and a superior grade by making chemically a mixed zinc and barium pigment.

Missouri continued to lead in the production of barytes in 1922, but Georgia was a close second. More than three-fourths of the total domestic output for the year came from these two States.

The imports of crude barytes in 1922 amounted to 23,239 short tons, valued at $104,680 at the foreign ports of shipment. This is about twice as much as the imports in 1921 but a little less than those of 1920. The barium products industries in the United States consumed 167,842 short tons of ore during the year. From this ore they made 46,176 short tons of ground barytes, 83,360 tons of lithopone, and 13,900 tons of barium chemicals, having a total value of $11,397,832. This is about one and one-half times the quantity of barium products manufactured and sold in 1921, but not so much as was made in 1920. The average annual value of lithopone has decreased from $139.69 a ton for 1920 and $121.45 for 1921 to $110.53 for 1922. Most of the lithopone produced in 1922 was made in Pennsylvania, Delaware, and New Jersey, in the vicinity of Philadelphia, where there are 8 operating lithopone plants or more than half the total number in the country.

OIL SHALE RETORT

At Latrobe, Tasmania, the Southern Cross Motor Fuels, Ltd., have put into operation a retort handling 30 tons a day of shale, from which 50 gallons of oil per ton is recovered. It requires only one man per shift to operate the retort.

CEMENT FROM SPENT SHALE

Experimental work conducted by the Building Research Board in Britain on Scottish oil shale after it has passed through the stills has showed that a hydraulic cement of superior quality can be made from it. The cement when set is of a reddish colour and is harder than Portland cement.

RECONSTRUCTION AT LENS

The shafts and surface equipment of the coal-field at Lens, so thoroughly destroyed during the war, are now well on the way to complete rehabilitation. The huge central power and gas station at Vendin is once more in service, and the temporary head-frames at the collieries are giving place rapidly to the permanent reinforced concrete structures that now are the vogue. The battered mining villages so well known to many Canadian mining men are also patched up or rebuilt, as the case has required, according to recent information.

MANGANESE PROSPECT IN NOVA SCOTIA

Work has been going on steadily at the property of the Aylesford Manganese Mining Company, which is located about three miles south of Auburn, Nova Scotia. The engineer in charge reports that developments to date are quite satisfactory.

The mining of chrome and nickel ores in New Caledonia is reported as improving steadily. The Thio nickel works are running at full capacity.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

QUEBEC

There has been a general revival of interest this summer in the eastern end of the gold belt in northwestern Quebec, to which Amos on the Canadian National Railway is the chief point of entry. In fact there appears to be about as much activity in this older and more readily accessible part of the gold belt as in the more recently discovered area centred round Rouyn township.

The Duke of Manchester has extensive holdings in this region, and has fifteen or twenty men at work on them. The land is held by a company called the Quebec Gold Rand, Limited, and comprises the following:—

Varsan township — Range 1, lots 1 to 7 (inclusive.)

Varsan township — Range 2, lots 1 to 10 (inclusive.)

Dubuisson township — Range 10, lots 1 to 8 (inclusive.)

Dubuisson township — Range 9, north half of lots 1 to 6 (inclusive.)

Fournier township — 700 acres in the northeast corner.

Malartie township — Range 1, lots 50 to 64 (inclusive.)

Malartie township — Range 2, lots 54 to 64 (inclusive.)

The Union Mines Corporation holds lot 30, range 8, Dubuisson township, and has twelve men at work under the direction of J. C. Yancey, who represents Chicago interests.

On Siscoe Island in Lake de Montigny five men are working.

NORTHERN ONTARIO

Porcupine. — The McIntyre Directors have declared a dividend of 5% payable September 1st to shareholders of record August 1st. The annual report of the company for the year ending June 30th, is not yet available, but the financial statement shows a decided improvement over the preceding year. Gross recovery amounted to $2,250,000, an increase of approximately $313,000. Operating costs were $1,335,000, leaving operating profits of $915,000. Non-operating revenue amounted to $57,000, while taxes for the period were $53,000, leaving net earnings, before depreciation, of $919,000. The company's June output was $247,000, but as the mill was shut down for a short period, due to power interruptions from forest fires, the rate of output was somewhat less than at the present time. Gross recovery is now understood to be approximately $300,000 a month.

The Hollinger has declared the regular four-weekly dividend of 1 per cent, payable August 13th, to shareholders of record July 26th. The company has awarded a contract for the construction of a dam and power house on the company's power lease on the Abitibi River to Sir. Wm. Arrol, Limited, of London, England. This contract involves approximately $1,000,000, but the total cost of the development will be about $3,000,000.

The quarterly statement of the Dome for the three months ending June 30th shows gross profits of $543,880, against which has been charged $138,000 for depreciation and $25,000 for Tax Reserve, leaving $380,280 as net profit. This quarter covers a period, however, during which the output was reduced on account of a shortage of power, and earnings are now running at a much higher rate, the June output being over $420,000. The financial statement shows approximately $4,000,000 of current assets, which includes a Dividend Reserve Fund of $1,041,000, Bonds to the amount of $1,213,000, Call Loans of $750,000, Cash $241,000, Bullion $229,000 and Inventories of $345,000. The cross-cut on the 12th level has penetrated the ore-body recently found by diamond drilling.

A Conciliation Board, consisting of Mr. Balmer Neilly, representing the operators, Mr. Thos. Ryan, representing the miners, and Mr. McG. Quirk, of Montreal, as Chairman, is now sitting in Timmins. The Board will deal with the demand of the men for an increase in wages of 20 cents a hour.

Quinze Power. — The Quinze Power Company has started construction of the steel tower transmission line to Porcupine, and it is hoped to erect from three-quarters of a mile to a mile of line perday. A large number of men are working on the power site on the Quinze River, and in about a month the contractors expect to be pouring cement for the dam. At present over 5,000 h.p. of hydro-electric power is available in Porcupine that is not being used. The Northern Canada Power Company is delivering a total of 17,000 h.p. to the mines.

South Lorrain. — The Mining Corporation, which is operating the Trout Lake property in South Lorrain in conjunction with English financial interests, has attained a depth of over 100 feet in the new shaft At a depth of about 50 feet some silver was encountered. On the company's own properties, including the Frontier, in South Lorrain, the new three-compartment shaft has reached a depth of 550 feet, and two new levels are to be opened up. It is expected that within a couple of months these two new levels will be producing ore. To date very little stoping has been done on the properties, but with the ore obtained from development work and a small amount of stoping on two shoots, the company has derived sufficient revenue practically to pay for the properties and for all the work done, amounting to nearly $750,000. There is a strong probability that the revenue from the South Lorrain properties will enable the company to resume dividend payments in the near future. It is stated that the new Ontario Government proposes extending the Nipissing Central Electric Railway to South Lorrain. If this is done it will permit the Mining Corporation to haul its ore to Cobalt for treatment, and as this company treats customs ores in addition to its own, it would enable any producer in South Lorrain to market any tonnage that

might be available. If such a railway is not built, it is probable that the Cobalt mill would have to be scrapped and a smaller plant built in South Lorrain. This would be an unfortunate event for the Cobalt district, because the Mining Corporation mill is now the only centrally located customs plant to which leasers and small producers can ship.

Gowganda. — The Castle property in Gowganda is obtaining high-grade ore from its lower levels and results on these levels to date are stated to be up to expectations.

Larder. — The Associated Goldfields at Larder Lake claims to have developed about 800 feet of ore of an average grade of $8.00, the width being from 15 to 20 feet. The vein has been opened up on several levels and the greatest amount of work has been done at 375 feet. The company has approximately half a million dollars of cash on hand, which it is expected will be sufficient to carry on further development and build a mill, and no new issue of stock is contemplated at present. The company has about 22,000,000 shares outstanding.

The report of Mr. M. W. Summerhayes on the Argonaut Mine has been published. This report shows estimated ore reserves of 39,000 tons, having an average value of $18.20 a ton, being a total of $710,000. Operating costs, without depreciation, are estimated at $6,80, and the net profit is estimated at $7.00 a ton. This report was written on March 31st, and since that time a good deal of work has been done on the 500-foot level, which has added very materially to the ore reserves. On May 31st the company had cash assets of $92,000, which was expected to be sufficient to carry operations through to the time when they will be on a profit producing basis. The mill is now operating.

Kirkland. — During the first half of July the Teck-Hughes produced approximately $46,000, or at the rate of about $100,000 for the month.

Mr. Ferguson and the Mining Act. — In a recent interview the Hon. Howard Ferguson forecasted some changes in the Mining Act, which it was believed would encourage work on mining properties. It is probable that the present period of five years during which assessment work may be done on claims will be shortened, in order to encourage exploration and development on new properties. He also stated that steps would be taken to prevent the fiasco of a couple of years ago, when a large number of patented properties, including at least one producing mine, were thrown open for restaking on account of the failure to pay the acreage tax. Provision will be made to prevent any sudden forfeiture of patented properties for this cause. It is also believed that the Government has in view the giving of greater publicity to Northern Ontario Mines in United States and England, from where it is expected that considerable capital for development will be derived.

OCHRE IN NOVA SCOTIA

A discovery of excellent ochre (raw sienna) was recently made near Ellerhouse Station on the Dominion Atlantic Railway in Nova Scotia. The color is uniform throughout, with very little gritty matter. The material can be burnt to produce a variety of colors, from reddish brown to black. Prospecting is still going on.

BRITISH COLUMBIA

Developing Portland Canal Properties. — W. R. Wilson, President and General Manager of the Crow's Nest Pass Coal Co., a large shareholder in the Premier Gold Mining Company, a prominent and active member of the Canadian Institute of Mining & Metallurgy, and one who is financially interested in a number of promising mining prospects in different parts of the Province, visited Vancouver and Victoria in July. He was in Vancouver at the time of the visit of the President of the United States and made a short stay in Victoria, chiefly to discuss mining matters with Hon. Wm. Sloan, Minister of Mines. These had to do principally with the opening up by roads and trails of the Portland Canal Mining District where Mr. Wilson's interests extend materially beyond the Premier Mine. He has undertaken responsibilities in connection with the development of the "Big Missouri" Group and it would seem that, as this work proceeds, the enterprise of its promoters is becoming more and more justified. Mr. Wilson has every confidence in this mineralized zone. He looks to see other large producers follow in the wake of the now famous "Premier"; but the nature of the country and the geological pecuniarities, in his judgment, have made it a camp for the man with capital. The miner of small means has in the past and will in the future find it difficult to make satisfactory progress. Large expenditures will have to be made on the properties adjacent to the Premier Group before the mining possibilities of the section will be ascertained and these, it is learned, are to be carried out without loss of time. If, as it is hoped, these demonstrate the continuity of the vein matter at depth, the life of the camp, as one of the important producers of the American continent, will be assured far into the future.

Mr. Wilson's Work at Fernie. — Few appreciate the value of the work Mr. Wilson and his associates are doing for the mining industry of this Province. For many years Mr. Wilson, who has the reputation of being one of the best practical coal mining engineers of Canada, had been engaged almost exclusively in the opening up of the coal measures of the Crow's Nest Pass District. This is a field of wonderful potentialities. Just how many distinct seams of coal there are does not even yet appear to have been definitely established; but it is said that forty-two have been noted. It is the one part of Western Canada where Cretaceous and Tertiary formations have been found outcropping in close proximity to one another. There is enough coal of the best quality to supply the largest and the most exacting market and a substantial part of British Columbia's coal production comes from the Crow's Nest — 554,361 tons of last year's production of 2,580,915 tons — still, mining operations are attended by difficult problems. The friable and gaseous nature of the coal and the tremendous overhead burden on the seams have given Mr. Wilson many anxious moments and have caused him to give of his best effort so to lay out his operations as to ensure the safety of the workers and to provide for a maximum recovery. In dealing with the complexities of the situation he has received, and has accepted in the best spirit, the co-operation and assistance of officials of the Department of Mines. Results of late years

seem to warrant the belief that the best possible methods, having in mind the local conditions, have been evolved and that the field is in shape, when the market and industry warrant, to double, treble, or quadruple its output.

Coal Profits Develop Metal Mines. — Achievement in the coal mining field led to investment, timely and well judged, in metalliferous areas. The outcome of the part taken by Mr. Wilson and his associates, Messrs. Trites and Wood, in the "Premier" now is a matter of history. But the making of a fortune does not enthuse a man of the type of Mr. Wilson as much as the satisfaction that comes of accomplishment. Increased income means added opportunity. Hence he is found re-investing in the Portland Canal District. Nor are he and his associates confining their attention to that section. They have bonded the Windpass coal mine, Chu Chua, near Kamloops, and have options on properties in the newest provincial mining region, the Whitewater. In the opening up of the former they had with them the late General R. G. E. Leckie, who died some weeks ago with tragic suddenness. Since his demise operations have been proceeding and Mr. Wilson states that the results are "very encouraging." To one familiar with Mr. Wilson's characteristic conservation these words mean much more than they usually are accepted as implying.

Fish Creek Mine Changes Hands. — Samuel I. Silverman, on his return from a visit to the Portland Canal Mining District, announced that the Fish Creek Mine, an option on which was obtained by the American Mining & Milling Co. about a year ago, and which is situated on the Alaska side of the Salmon River, has been taken over by London and New York interests. The latter, it is stated, are absorbing the organization to which the property was optioned and will proceed with the development of the Fish Creek holdings. While Mr. Silverman was in the North arrangements were made to commence work on the driving of a 2,500-foot tunnel.

Strike on Bear River. — Excitement has been caused in Stewart by the report of a strike of high-grade ore on the Dunwell Mine, Glacier Creek, Bear River. No. 2 Tunnel, when driven some 280 feet, encountered two veins. In cross-cutting these, ten feet of ore carrying exceptional values in gold, silver and lead were encountered. This property is controlled in Victoria, the Stewart Land Co. being largely interested. The Company's manager confirms the report outlined and is asking that the provincial Government furnish aid for the improvement of transportation facilities in order that development may proceed on a larger scale than heretofore.

Progress in East Kootenay. — A. G. Langley, resident mining engineer at Revelstoke, has returned from a tour of the East Kootenay mining districts. He states that the Kimberley concentrator, Consolidated Mining & Smelting Co., is nearing completion, that it is the last word in modern metallurgical practice and a credit to the engineers and metallurgical staff of the Company and that, with it in operation, the output of lead and zinc in Canada will be largely increased. The Paradise Mine, Windermere, will resume shipments shortly, he states. Bad mountain roads have interfered with the work. Operations are starting on properties on Boulder, Horse Thief and Number Three Creeks. O. C. Thompson will commence the construction shortly of a 100-ton concentrator to treat the ore of the Stemwinder Mine, where there is a large tonnage of ore similar to that of the Sullivan Mine. Mr. Langley also said that Dr. Bancroft, of the Canadian Geological Survey, and party are mapping the Windermere country.

Coast Magnetites Promise Well. — Dr. G. A. Young, who is making a survey of the iron ore deposits of British Columbia with a view to reporting as to the assured tonnage of economic ore available for the support of an iron and steel industry, returned from the field for a few days recently to confer with Dr. Charles Camsell, Deputy Minister of Mines at Ottawa, during the latter's visit to the Coast. Dr. Young is now engaged in an examination of coast magnetite properties. It is understood that the results of the survey so far are very encouraging.

Trail Ore Receipts. — Ore receipts at the Trail Smelter, Consolidated Mining and Smelting Co., for the week July 8 to 14, totalled 9,249 tons. For the first time in many weeks a Rossland Mine figures as a shipper, the Gold Drop having conrtibuted 5 tons The details follow:

	Tons
Alamo, Alamo	48
Company Mines	8,618
Gold Drop, Rossland	5
Lone Pine, Republic Wn.	224
Quilp, Republic Wn.	57
Rosebery-Surprise, New Denver	92
Silversmith , Sandon	43
Standard, Silverton	162
Total	9,249

Cork-Province Shipping Again. — The Cork-Province Mine, it is reported, has shipped its first car of ore to the Trail Smelter, since resuming operations. Two more are ready for hauling, states W. H. Burgess, secretary of the Company, and regular shipments are promised. Mine and mill are working smoothly and for the present zinc concentrate is to be stored.

FUEL EFFICIENCY AT BRICK KILNS

Operators of numerous brick plants are putting into practical application the fuel-efficiency data obtained as the result of the series of burning tests at industrial kilns recently conducted by the laboratory car "Holmes" of the United States Department of the Interior, in co-operation with the heavy clay trade associations, according to reports submitted to the Bureau of Mines by its field agents.

A notable example has been reported to the Bureau from Birmingham, Ala., in the case of an operator of two brick plants near that city who had been operating his kilns without especial regard to modern, efficient methods. This operator, being a member of certain brick trade associations, receives through these associations the results of improved methods of burning as developed by kiln-burning tests conducted under the direction of the Ceramic experiment station of the Bureau of Mines at Columbus, Ohio. Against the advice of the old practical burner and everyone else connected with the work, the superintendent at one of the plants decided to try out the method as outlined by the tests made by the Bureau of Mines. The results were

more than satisfactory. At this plant it formerly took about 9 days to burn a kiln with a consumption of over 1,400 pounds of coal per 1,000 brick. The company had contemplated building more kilns to take care of the demand. They now burn off the kiln in 5 or 6 days and use under 900 pounds of coal per 1,000 brick. Instead of building more kilns, some of the other kilns are now idle, while the plant still maintains its capacity.

THE CONVERSION OF DIAMOND TO GRAPHITE AT HIGH TEMPERATURES

Under this title M. DeKay Thompson and P. K. Frolich gave in a paper before the American Electrochemical Society in New York, May 3-5, an account of experiments made to determine the temperature at which the change of diamond to graphite begins to show. It has long been known that this change takes place at the temperatures of electric arcs and electric furnaces, but contradictory statements have been made as the temperature at which diamond ceases to be stable. The authors, using a small Arsen furnace fitted with appliances for securing constant temperatures, found that diamonds change slowly to graphite at 1650 deg. C. and at 100 degrees higher the change takes place 26 times as fast.

POSITION WANTED — A Canadian Mining Engineer, graduate of Canadian University, specialized in the geology, development and operation of iron mines on a large scale in the Western States, desires to return to Canada to follow up the iron industry. Can give best references. Apply Box 602, Canadian Mining Journal, Gardenvale, Que.

FOR SALE

Entire Equipment of our Concentrating Plant at Black Lake, Quebec

including:

Three (3) Gould Triplex Pumps
Two (2) Hardinge Mills
Two (2) Farrell Crushers
Two (2) 24'' Duplex Callow Screens
Two (2) Dorr Slime Thickeners
Ten (10) Deister Concentrating Tables
Two (2) Wilfley " "
and much miscellaneous equipment

Everybody has the Spirit

OF CO-OPERATION

In Planning to Make

AMERICA'S MOST IMPORTANT INDUSTRIAL EXPOSITION

The most successful ever held. It promises to be epochal in its scope and in the character of exhibits.

9th NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES

GRAND CENTRAL PALACE, NEW YORK

SEPTEMBER 17th - 22nd 1923

Talk about it NOW and have your people ready for it.

Those who realize how much the progress of ALL INDUSTRIES depends on chemical knowledge should point out to other executives the great benefits to be gained from this exposition.

Remember that it is not an exposition restricted to the technical field of chemistry. Chemistry is the basis, and vital problems of every conceivable industry are covered in various ways.

This is an INDUSTRIAL exposition which will be helpful to every business man in the country who attends it.

For further information address National Exposition of Chemical Industries, Grand Central Palace, New York.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. H. Mills, Minister. DEPARTMENT OF MINES *Thos. W. Gibson, Deputy Minister*

Hon. CHAS. McCREA, Minister

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver mines of Cobalt occur in these rocks; so also do the far famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	$22,388,383	1921	48,128,387
	Dividends.		

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

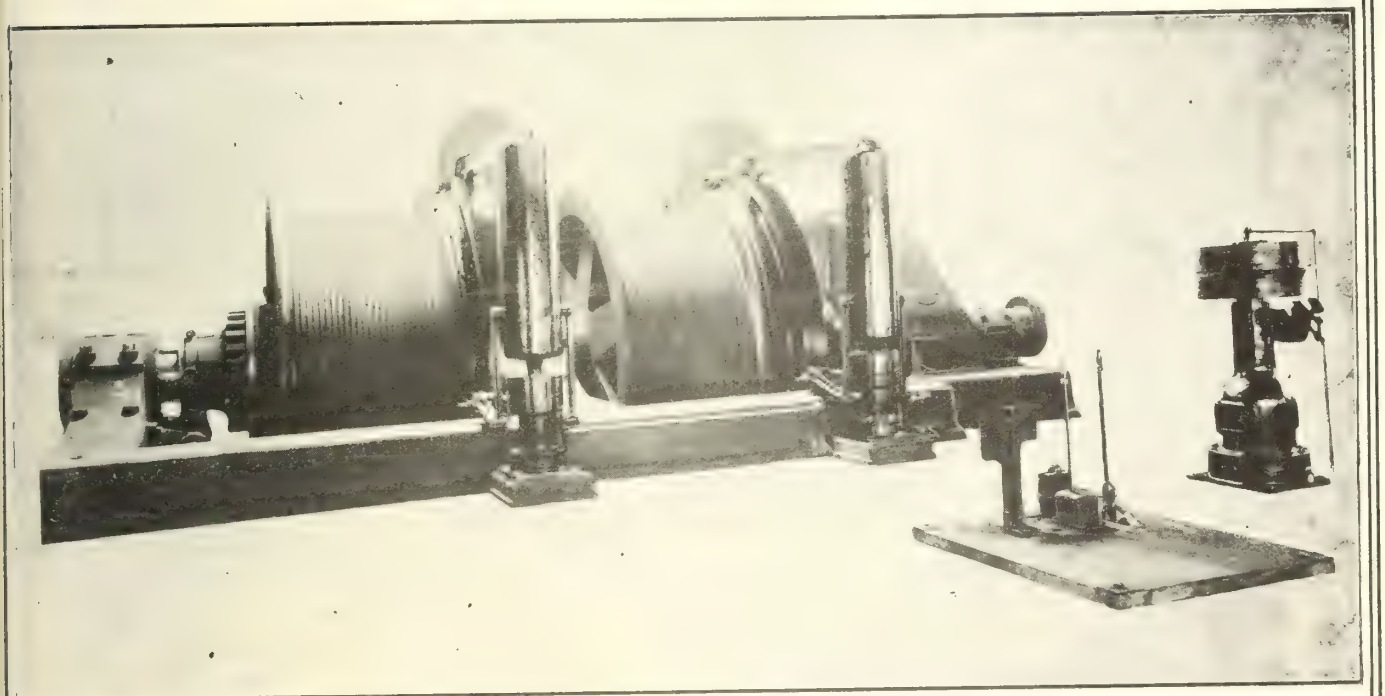
BY PURCHASING

"Ottumwa" Hoists Built in Canada



This Hoist hauls a 15 Ton Load on a 45° Slope at 1600 ft. per minute. Drums 107" Dia. by 50" face. 1¾" Rope. Driven by 900 H.P. Motor Through Single Reduction Herringbone Gears. Clutches and Brakes Oil Operated.

One of several exclusive features of the "OTTUMWA" Hoist is the PROPORTIONAL PRESSURE CONTROL for power operated brakes. Successive positions of the hand levers give definite and increasing increments of braking effect. A simple and reliable device which effectively replaces the usual complicated gear with superior results. Has proved its worth on many installations.

CANADIAN VICKERS, LIMITED

MONTREAL, QUE.

INGERSOLL-RAND has always realized the need of a specific type of drill for each kind of work and consequently builds a variety of types and sizes. **Each of the many machines is designed for a special duty and the entire line covers every class of rock drilling on land or water.**

Some of the Company's latest types are as follows:

"Jackhamers" made in five sizes, ranging in weight from the 21 pound "BAR-33" to the 75 lb. "DDR-13" and meeting every requirement for drills of this type.

"288" and "298" Convertible Drifting and Sinking Drills for drifting, tunnelling and the heaviest class of down hole drilling, to which a hand-held drill can be applied.

A Rock Drill for Every Requirement

78, 88, 98 and 188 Drifters — Powerful high speed drills designed particularly to meet conditions in Canadian mines. After much experimenting a steadily increasing number of properties are standardizing on these machines.

X-70 Leyner Ingersoll Drifters — The largest and most powerful hammer drill made — Recommended for the largest tunnels and the deepest and heaviest drilling. Used both for tunnel work and for large open cut work.

S-80 Drifter—A high speed drill of moderate weight with independent rotation. Recommended when the highest drilling speed and independent rotation are of primary importance.

Type "CC" "Stopehamers"—Designed for all classes of drilling in which holes are 20 degrees or more above the horizontal. Furnished in both wet and dry models.

"Little Giant" "54" All Steel Piston Drills for canals, railroad cuts or other heavy excavation work. Built for wet or dry drilling and for use on air or steam.

Class "H-66", "H-67" and "H-68" Deep Hole and Submarine Drills — Designed for the heaviest class of deep hole drilling on land or water: can be run on air or steam and will bottom a 5 inch hole at 60 feet.

Our nearest branch will gladly give you impartial help in selecting the type best suited to your needs.

Adding Impetus To The Development Of Mining

The development of Canada's enormous natural resources will affect her whole future. Her vast mineral wealth, as yet practically untouched, is to-day attracting world-wide interest from far-seeing investors.

It is appropriate that the Imperial Bank, whose policy has ever been to concentrate exclusively on Canadian affairs, should be powerfully furthering that interest. This Bank, by placing branches at strategic points throughout the mining districts, has materially aided the whole industry.

Those who contemplate becoming connected in any capacity with mining would be well advised to take advantage of this Bank's facilities.

OUR CONTRIBUTORS

The Canadian Mining Journal welcomes to Canada the members of the American Institute of Mining and Metallurgical Engineers who will gather in Toronto next week for their summer excursion. In order to make this welcome tangible, it has enlisted the aid of a number of men prominent in the mining and metallurgical circles of Ontario and Quebec in preparing a series of articles describing the mining camps to be visited. We shall not try to steal their thunder, (a habit imputed to all editors), but shall merely mention them in sequence.

On these editorial pages Hon. Charles McCrea, newly appointed Minister of Mines for Ontario, and Hon. J. E. Perrault, Minister of Mines for Quebec, join us in welcoming our American guests.

After a short (and select) history of certain notabilities to be encountered on the trip, we present a general description of Ontario's mining industry by Mr. Thos. W. Gibson, who has guided its destinies with unwavering hand for longer than we can remember. We have made capital of the good nature and public spirit of a number of the members of his staff; Dr. Miller summarizes the geological features of the North country; Mr. T. E. Godson gives the main features of the Mining Act, and Mr. T. F. Sutherland describes the mines inspection system, for whose administration he is responsible, and then tells what a fine place Ontario is for the miner.

Sudbury is the first camp to be visited. Mr. Alexander Gray, now of Montreal and formerly of Colorado, Australia, the Rand and London, gives the record of this famous camp, and Mr. Sutherland touches on its history.

The next stop is at Cobalt. Dr. J. Mackintosh Bell has prepared a study of this and the adjoining silver areas that will stimulate thought and should stimulate discussion. Our Northern Ontario correspondent gives a resumé of Cobalt's history and record of production, as well as that of the gold district to the north.

Kirkland Lake and Porcupine are still in the making. Mr. Balmer Neilly, secretary of the Ontario Mining Association, describes these briefly, with an eye to their future. Professor George J. MacKay, of Queen's University, compares Ontario gold metallurgy with that of the Rand, where he spent a number of years employed in the mills. Mr. A. G. Burrows, who has followed the progress of the Porcupine camp from its discovery and is now engaged in a re-examination of the field for the Ontario Department of Mines, describes its geological features.

Quebec's mining industry is characterised by Mr. John E. Dresser, President of the Canadian Institute of Mining and Metallurgy, whose acquaintance with it has been long and intimate. Mr. A. O. Dufresne, the active Assistant Superintendent of Mines for Quebec, describes the new Rouyn gold field in the north-western part of the province, whose development will, it is hoped, do much to stimulate the search for minerals throughout Quebec's vast, unexplored hinterland.

The asbestos district of the Eastern Townships is the last camp on the tour. Mr. Norman R. Fisher has prepared a description of it that will effectively guide the excursionists through the pits and the mills.

This issue of the *Journal* demonstrates clearly the fact often repeated by editors and seldom realized adequately by others, that technical journalism is a coöperative venture in which the technical men of the profession are jointly responsible with the publishers. We thank our contributors in this instance, many of them busy men who can scarcely afford the time to write, for having made an addition, not only to the technical literature of their country, but also to the success of our visitors' summer excursion.

THE ITINERARY

This issue of the *Journal* is designed as a guide to the mining camps to be visited by those attending the summer excursion of the American Institute of Mining and Metallurgical Engineers during the next two weeks. Gathering in Toronto on August 20th, the excursionists will inspect the mines, smelters and mills at Sudbury, Cobalt and South Lorrain, Kirkland Lake, Porcupine, and the Thetford district. They will go from Porcupine to Quebec via Cochrane and the Canadian National Railway, and after a day in Canada's oldest city will proceed to Montreal, via Thetford. In Montreal technical sessions will be held on the 30th and 31st of August.

Committees of mining men and geologists have prepared programmes for the visitors at the various Canadian centres. The actual visits to the numerous places of interest will be the most important and the most attractive feature of the excursion, of course, and the printed page will no doubt prove to be an aid in the tour of inspection. In the August issue of *Mining and*

Metallurgy, the official publication of the American Institute, there are three papers specially prepared for the purposes of this excursion, viz: "Notes on the Mining Industry in Canada," by Edward K. Judd; "Kirkland Lake Gold Area," by Percy E. Hopkins, of the Ontario Bureau of Mines; and "Notes on the History of Porcupine," by L. D. Huntoon.

WELCOME TO THE PROVINCE OF QUEBEC!

To the President and Members of the American Institute of Mining and Metallurgical Engineers.

Gentlemen:—

As official head of the Department of Mines of the Province of Quebec, it becomes my pleasing duty to extend on its behalf, through the columns of the *Canadian Mining Journal,* a very cordial greeting and the warmest possible welcome to the members of your excursion party, upon the occasion of their approaching visit to our Province.

You come to us after visiting the silver mines of Cobalt and the gold mines of Porcupine, which not only adjoin the Quebec boundary, but whose mineral bearing formation extends for miles into our Province, and where already 1,200 claims have been staked in Rouyn Township alone, placing over 200,000 acres under permit. You will thus see, in virgin condition, the future site of the most promising gold fields of the immediate future; while at Thetford and Black Lake in the Eastern Townships you will be in the heart of the greatest asbestos mines of the world, whose wonderful yield is a remarkable testimony not only to the richness of the mineral deposits, but also to the liberal mining laws of our Province, which are framed with a view to the encouragement of prospecting and production, and which offer absolute security of title to the successful prospector and operator.

Hoping that you will one and all enjoy your visit to our Province and will find here much in our mineral deposits and liberal mining laws to commend them to your favourable consideration and warm recommendation,

I have the honour to be,

Yours very sincerely,

(Signed) J. E. PERRAULT,

Minister of Mines.

Quebec, August 10th, 1923.

MESSAGE FROM ONTARIO'S MINISTER OF MINES

To the Members of the American Institute of Mining and Metallurgical Engineers:

I bid you welcome to our far-flung Empire of the North, whose mineral riches you have come to see.

You will find at Sudbury the largest and most productive source of the world's supply of nickel; at Cobalt a silver camp whose mines, after twenty years' operation, are still producing freely, and where recent discoveries rival in richness the finds that electrified the world in 1903, 1904 and 1905; at Porcupine a group of gold mines of the first rank, one of them yielding a million dollars' worth of gold per month; and at Kirkland Lake half a dozen deposits producing bullion. Moreover you will find other Porcupines and Kirklake Lakes in the making.

Ontario is in a unique position as regards gold production; while in every other country it is declining, here it is increasing. A significant fact is that our gold ores are not confined to one or two isolated patches, but are found over a wide stretch of country extending for hundreds of miles. The great pre-Cambrian shield of Northern Ontario, much of it yet untrodden, provides one of the best remaining areas in the world for the searcher after gold and silver.

Here is an inviting field also for engineering skill and capital. Our laws do not discriminate between citizens of the United States and British subjects, or between American capital and British capital.

The mining regulations are liberal. Our institutions are not a passing phase; they are stable. Our system of mine taxation is based on net profits, and the welfare of the mining industry forbids hasty or ill-considered attempts at change.

Beneath the summer sky of our northern clime you are almost certain to be favoured with good weather. I sincerely hope you will enjoy your visit to the full, and I believe that in returning from the land of the Union Jack to that of the Stars and Stripes, you will do so feeling as did the Queen of Sheba, that the half had not been told.

C. McCREA.

Minister of Mines.

Toronto, August 11th, 1923.

WELCOME THE A. I. M. M. E.

From yon Republic, strong, and wide, and free,
The very home of human liberty,—
Where reigns without a mitigant condition
The most uncompromising prohibition,—
We welcome you as leaders, wide of brow,
Whose mission is to show us why and how.
Ambassadors of Progress, we embrace ye!
We know that virtue and true knowledge grace ye.
That erudition is your middle name,
And your repute a synonym for fame.
Whether in Montreal or South Lorrain,
Whether on steamer or aboard the train,
We ask you to consider all your own,
To make your needs of any nature known.
(A hint, a word, the thoughtful host suffices,—
Folk cannot live on soda or on ices.)

J. C. M.

Peripatetic Personalia

"The proper study of mankind is *man*."

Alexander Pope said a mouthful when he wrote that ine! We agree with him so heartily that, for the benfit of our visitors, members of the American Institution of Mining and Metallurgical Engineers, we have ompiled a short descriptive catalogue of a few outtanding Canadian mining men. Our sins of commission are glaringly apparent hereunder. Not so our ins of omission: for such a contracted list embraces nly types. Dozens, scores, nay, hundreds, of notbilities have necessarily been excluded. A complete "Who's Who" would be an appalling tome. Regard vhat follows, therefore, as a "Who's What" — a ualitative, rather than a quantitative, effort.

We have grouped our exhibits geographically, without any regard to precedence or seniority.

TORONTO

Dr. W. G. Miller—

"That leader of the rocky clan, respected Willett Miller,
"Who won his name and fame withal by diagnosing siller."

This doggerel very inadequately indicates Dr. Miller's claim to fame. It is true that, professionally, he stood *in loco parentis* to Cobalt. But his name and fame, and his place in the affections of Canadian mining men, had been won whilst Cobalt was still Long Lake. Canadian geology owes much to Dr. Miller. Those who owe him nothing at all are such of his fellow-geologists as have "started sumpin'" in the way of an argument with him. A synthetic Miller would result from some such recipe as this:—

Take—210 pounds best Scottish-Canadian brawn:
Stir in — a flair for handling men and affairs:
Season with discretion and the slyest sense of humour obtainable: and — garnish with an irresistible smile.

J. B. Tyrrell—

"A man who knows each rock and squirrel
"Throughout the North, is J. B. Tyrrell."

Or if he doesn't, he should. Tyrrell, though not notably averse from the fierce light that beats upon the known, is a plain, blunt man who can eat prunes and goo with anybody. Shakespeare notwithstanding, his honours have been in part achieved and in part thrust upon him.

Frank C. Loring—

"A primrose by the river's brim
"A yellow primrose is to him,—
"And infinitely more."

The shade of Wordsworth may resent this, but Mr. Loring will not, when we add that he is an old-time honest-to-goodness miner: a man who has seen many a boom rise and bust and who has survived honorably the vicissitudes and mutations of Canadian metal mining. Loring might have been an artist, hence the prefatory profanation of the poet. He seeks not the limelight.

T. W. Gibson—

"That man was famous and was had
"In es-ti-ma-ti-on
"According as he lifted up
"His axe thick trees upon."
(Covenanters' Psalm.)

The sturdiness of Mr. Gibson's moral fibre is attested by the fact that he has administered the affairs of the Ontario Department of Mines for Lord knows how long, without noise or blather. Notwithstanding Mr. Gibson's calm restraint, we should rather guess that he would have been a holy terror swapping buffets with obsidian weapons in the Neolithic Age.

H. E. T. Haultain—

"Like the war-horse he sniffeth the battle afar;
"He champs at his bit, and he hankers for war."

Which means simply that Professor Haultain, who occupies the Chair of Mining at the University of Toronto, is guaranteed not to go out of his way to avoid a row. Haultain, beloved of his students, is devoted to them and to comminutive curves and abrasive abstractions. Though a high explosive, he is not smokeless.

G. R. Mickle—

"Assessor Mickle, saturnine, severe,
"But damnably precise, correct, and clear!"

Mr. Mickle's ungrateful task is to assess for the Ontario Government the taxability of mining companies. He does his duty unflinchingly, but not provocatively. Indeed he is a round peg in a circular hole.

Balmer Neilly—

"Show me a calm man, I'll show you one calmer;
"Show me Gilead's balm, and I'll show you Balmer."

When the Ontario Mining Association (a protective body) was formed, Balmer Neilly, himself an operator of no mean repute, was selected as the Association's inside guard, flying wing, glad-hand artist, and strategist. It is not to be doubted that he was instructed to counteract the Provincial Assessor's nefarious activities. He has won his spurs, but he has never used them on the Assessor.

Dr. J. Mackintosh Bell—

"Suaviter in modo, et fortiter in re."

Dr. Bell is the Canadian representative of goodly Old Country interests. He is a shining example of the mining engineer as an administrator of large business. He is the official connecting link between the sedate Institution of Mining and Metallurgy (London) and the Canadian body of the same ilk. Mackintosh Bell has a skeleton in closet — as all normal beings have. He runs to literature in his leisure. However, he has few spare moments.

T. F. Sutherland—

"Stern Instrument of Law, thou and thy minions
"Regardless are of other folks' opinions."

Since Chief Inspector of Mines Thomas F. Sutherland is of old Presbyterian stock, he must be a Calvinist. We may thus assume that he is a fatalist. In any case he deals with fatalities. Thomas is Didymus when it comes to alibis — Aquinas when dealing with subterfuges. He is not at his best on formal occasions. He can detect a joke.

Hon. Charles McCrea—

"And our eyes on all his motions
"With a mute observance hang."

The Hon. Mr. McCrea, not yet put to the proof, will, we hope, keep his ear to the ground and his eye on these columns during his tenure of the office of Minister of Mines for the Province of Ontario.

COBALT

Arthur A. Cole—

"To get some concept of the North, the whole
"Far-stretching North, confer with Arthur Cole:
"Take him as guide, philosopher, and friend,—
"A man of information without end."

Mr .A. A. Cole, Mining Engineer to the Temiskaming and Northern Ontario Railway Commission, is more than a mere person,—he is an institution, a thesaurus. He worships at the shrine of Arcturus. The North is his mistress, a mistress coldly chaste and imperious.

James Denny—

"For problems touching chemistry, or any
"Discussion of refining, go to Denny."

When a painfully respectable University goes out of its way to create a new kind of degree wherewith to decorate a man, then it's going some. Mr. Denny has been so decorated. He is the Nipissing's metallurgist. The good Lord endowed him with brains and modesty in equal parts. His modesty is remarkable.

M. F. Fairlie—

"The Grace of God it worketh woundily,—
"Didna I mine, 'twad be the Kirk for me!"

A prepossessing young man, with an engaging smile, is Mr. Fairlie. The Mining Corporation entrusts him with a large part of its affairs.

Cyril W. Knight—

"Ah, Love could you and I with Him conspire
"To grasp this sorry scheme of things entire—"

At least Mr. Knight, formerly Dr. Miller's assistant, now absorbed by Nipissing, would be able to supply most of the inside dope about the interior geological economy of Cobalt.

PORCUPINE

Richard Ennis—

"Smile and the world smiles with you."

The General Manager of the McIntyre has not always lain on a bed of roses. Without danger of fracturing the eternal verities, Mr. Ennis may be denominated a good sport. Naturally he is not deficient in administrative acumen.

A. F. Brigham—

"A hell of a job old Atlas had!
"But he had nothing on me, begad!"

To manhandle the Hollinger is no child's play. Although Mr. Brigham sometimes makes a noise like a weary Titan, he looks awfully well in golf "pants."

H. DePencier—

"Lo, in the middle of the wood,
"The folded leaf is wooed from out the bud."

Mr. DePencier is the General Manager of the Dome. Mr. DePencier's genius for administrative detail has been developed gradually and soundly. We, who write this, have watched his growth in grace with admiration.

MONTREAL

John A. Dresser—

"Twinkle, twinkle, Prester John!
"What's the jape you're bent upon?"

Mr. Dresser, it need hardly be stated, is President of the Canadian Institute of Mining and Metallurgy. A quondam professor, he is now a self-respecting mining geologist. He knows his work, and he knows human nature. This latter has taught him wide tolerances.

G. C. MacKenzie:—

"A cubit more, a cubit less,
"A stone or two of lean or fat.
"What matters it when all is said?
"A man's a man for a' that!"

The assiduous Secretary of the C. I. M. M. has borne patiently through life an irritatingly disrespectful nickname. Far be it from us to give it further currency. We merely rise to remark that any secretary of any Canadian technical society deserves the prayers of the congregation. "Spike's a good fellow, and 'twill all be well."

W. M. Goodwin—

"This wretched world is wrong, O, cursed spite!
"That I was ever born to set it right!"

This miserable paraphrase of the poet's noble lines is no more excusable than the mayhem that the Editor of the *Canadian Mining Journal* often commits on our manuscript. The young man who sets out to make this world better has our sympathy, but never our co-operation. Anyway, one cannot argue with an editor. If you get the better of him he won't publish your letter. The sad part of it is that Mr. Goodwin was once a God-fearing prospector.

Alexander Gray—

"Sir Oracle, I pray you, can you tell
"Precisely the formation down in Hell?"

In the proper person of Mr. Gray, free-lance and journalist at large, are combined two antithetical entities, the wise man and the wise guy.

Sir Stopford Brunton—

"If anyone can show you how to harrow net
"Profits from out a mine, it is the Baronet."

Though the exigencies of rhyme seem to have left no alternative, the sentiment expressed is, we doubt not, perfectly true. Sir Stopford is manfully living down his titular superfluity. A man can't do more than that.

John E. Hardman—

"John Hardman, O, my jo John,
"When we were first acquent
"You step was firm—'tis yet John:
"'Tis Time, not you, has bent!"

Mr. Hardman is one of the fathers of the C. I. M. M. His long attrition with his fellows has given him a polish that lies deeper than varnish. He is the post-prandial Chauncey Depew of the Institute.

SUDBURY

C. V. Corless—

"O, Elder Statesman, furrowed as to brow!
"Come off the roof, and join our party now!"

Dr. C. V. Corless is a scholarly, detached, much-appreciated citizen. He pilots the Mond Nickel Company through smooth and broken water. A former President of the C. I. M. M., his pronouncements carry weight with everybody save only a recalcitrant Scot whose name is Campbell.

OTTAWA

Charles Camsell—

"No thought of self, and no ambition sinister,
"Contaminates the Deputy of a Minister."

A long apprenticeship as a mining geologist, explorer, and so on, fitted Dr. Camsell to hold down the job of Federal Deputy Minister of Mines. A Deputy Minister cannot afford indiscretions of his own: he has to explain those of the Minister. He thanks High Heaven when the Minister realizes the depth of his own innocence of mining.

* * *

Editor's Postscript—

We ask the indulgence of our readers for the material published above. As a psycho-pathological phenomenon it may be of interest. Otherwise our only excuse for its appearance is the fact that it crept into the "forme" during our absence.

The Mining Industry of Ontario

By THOS. W. GIBSON*

Introductory

In Holy Writ, Canaan of old was pictured to the expectant Israelites as "a land whose stones are iron and out of whose hills thou mayest dig brass." A modern writer would hardly feel justified in using language so quaint, yet the underlying idea was sound. A land rich in mineral resources can justly lay claim to the possibilities of material greatness.

Canada as a whole is beyond doubt a rich mineral country, but it is rather striking how varied are the contributions to the common wealth made by the several provinces. On the eastern and western coasts, and in the Rocky mountains, are vast supplies of coal, which is entirely wanting in the central provinces of Quebec and Ontario. Quebec, Ontario and British Columbia yield copper, but on the western plains, save in Northern Manitoba, this metal is practically unknown. Silver is confined to Ontario and British Columbia, and as regards commercial production, the same may be said of gold. Nickel comes only from Ontario, and asbestos only from Quebec. Mineral deposits naturally have no relation to boundary lines; the key to their location is in the geological structure.

In the northern half of North America it is now recognized that the formations laid down and piled up in pre Cambrian times are *par excellence* the metal-bearing rocks of the region. By the same token, having been formed before vegetable or animal life appeared, the pre-Cambrian formations contain no deposits of coal. But of iron, copper, gold and silver there is abundance.

Iron Ore

Confining one's self to Ontario, it is undoubtedly true that her deposits of iron ore are very large. In many parts of Northern and Northwestern Ontario are found iron ranges of unusual dimensions. Unfortunately, they are in the main highly siliceous and low in iron. This is true both as regards magnetite and hematite, not to speak of siderite, though the deposits are largely of the first named variety. In the present state of the iron smelting industry, these ore-bodies are mainly to be regarded as a reserve against the time when progress in the art of reducing iron ore to the metallic form will permit of their utilization, or on the other hand until it has been shown that magnetic or other forms of beneficiation are commercially practicable. Advances in the latter direction undoubtedly are being made, and recent experiments with briquettes produced at Moose Mountain charged into the furnace along with good natural ore have given a product of high quality. Meantime, the blast furnaces of Ontario are forced to import from the United States practically all the iron ore they require, which is in the neighbourhood of one and a half million tons per annum.

Silver

In silver, Ontario has far surpassed in production all her sister provinces. The first good deposit was on Silver Islet, a small island on the north shore of Lake Superior, where in 1868 Thomas Macfarlane found a rich vein containing native silver. On being developed the ore was found to carry nickel, cobalt, arsenic and bismuth. The deposit closely resembled those found at Cobalt 35 years later. About three and a half million dollars' worth of silver was taken from the Silver Islet mine from first to last. The metal was also found on the mainland of Lake Superior, and several mines were opened up and a considerable quantity of silver obtained.

Consistent silver mining in Ontario began, however, with the discovery of phenomenally rich ore-bodies in 1903 near Long Lake (afterwards re-named Cobalt lake) during the construction period of the Timiskaming and Northern Ontario Railway. The richness of some of the ore was surprising, running up to and beyond 10,000 ounces of silver per ton. The veins were found mainly in conglomerate rock, but also in diabase and Keewatin. The key to the origin of the ore-bodies, as was soon determined by the Government geologists, was an intrusion of diabase that shattered and fissured the conglomerate and Keewatin and at or about the same time deposited silver in these veins or cracks. Production began in 1904, and up to the end of 1922, about 332 million fine ounces of silver have been recovered.

The veins are narrow, varying from half an inch to eight or ten inches in width, and are limited both in length and depth. Other constituents of the ore are cobalt, nickel and arsenic, all of which are recovered in refining the ores. These deposits have placed Ontario in a leading position so far as supplying the wants of the world with cobalt is concerned.

In the original Cobalt area, contiguous to the town of that name, the high-grade ores have for the most part been pretty well worked out, and the mines are now largely operating on low-grade ore. By using the flota-

* Deputy Minister of Mines, Toronto.

tion process it has been found profitable to treat wall rock containing as low as eight or nine ounces per ton, and also old dumps previously regarded as worthless. By this means, and also by an occasional discovery of rich veins not coming to the surface, or which had previously escaped notice, the life of the camp has been prolonged. Recently, developments at the Keeley and Frontier mines in South Lorrain, a subsidiary camp lying twelve or thirteen miles to the southeast and on the shore of Lake Timiskaming, have greatly helped in maintaining the district's silver mining industry.

The Keeley mine was deemed worked out many years ago. Its supposed failure brought the Farmers' Bank to grief and put its president in jail. In realizing the bank's assets, the mine was sold for a small sum and passed into the hands of an English company. The Company's manager, J. Mackintosh Bell, correctly interpreted the geology of the deposits, and persuaded his company to sink to a greater depth. They did so, and struck a large quantity of ore of extraordinary quality. On the adjoining Frontier mine, the Mining Corporation of Canada obtained like results and during the first six months of 1923 turned out no less than one million ounces of silver.

Romantic occurrences such as these sustain interest in Cobalt, and provide inducements for extensive schemes of prospecting by diamond-drill and otherwise, based on a close study of the geology.

Gowganda, lying north and west of Cobalt, has provided several deposits of similar ore. The principal one of these is the Miller Lake-O'Brien, a rich deposit operated vigorously for several years. The Castle-Trethewey also contains high-grade silver ore.

The Hollinger Outcrop in 1909

Gold

The prospectors who combed the rocks of Cobalt for silver wandered farther afield, and in 1909 struck rich gold ore on and near the banks of Porcupine lake. Fortunately, several of the discoveries fell into the hands of a group of men who had made a fortune at Cobalt, and were consequently in position to finance the development of a gold mine. Early efforts at mining were halted by the disastrous fire of 1911, in which practically all mine buildings in the new camp, and also many human lives, were lost.

It soon became apparent that the deposits were extensive and capable of being worked profitably. The Hollinger, McIntyre and Dome mines were developed, and production grew apace. The first named mine is worthy to be compared in point of production and value with any on the Witwatersrand. It has upwards of fifty miles of underground workings, raises and crushes 4,700 tons of ore per day, and has a monthly production of over $1,000,000. There is an extensive vein system, and predicated on a workable depth of 3,000 feet, General Manager Brigham has valued the total production at $450,000,000.

The McIntyre adjoins the Hollinger, and receives at depth some of the veins from the latter. Struggling to keep its head above water in the early years of the mine, Manager R. J. Ennis has brought the McIntyre through to an enviable position. Recently at a depth of over 2,000 feet an entirely new body of ore of good quality was struck. The production in 1922 was 103,819 ounces.

The Dome lies some two or three miles southeast of the Hollinger-McIntyre group. The mine receives its name from a dome-like mass of quartz which attracted the attention of the early prospectors. The "golden stairway" runs up the side of this dome, splashed and painted with native gold. Opened as a quarry, the Dome subsequently adopted the shaft-and-level system of working. It is now producing at the rate of between 200,000 and 300,000 ounces per annum. The geology of the Dome indicates that the porphyry intrusions have influenced the deposition of the gold, and in some of the lower levels very rich ore has been found.

In treating the Porcupine ores, ball mills are used for fine reduction, and cyanidation for recovering the gold. Stamps are being largely discarded, and the latest innovation is the substitution of rod mills for ball mills.

At Kirkland Lake there is a principal ore-bearing zone or "main break" running south of, and under, the bed of the lake itself. On this several mines have been developed, including the Teck-Hughes, Lake Shore, Wright Hargreaves and others. The ores of Kirkland Lake are richer than the ores of Porcupine, in some of the mines running up to $25.00 or $30.00 per ton. Further to the south a number of properties have been worked for a number of years with more or less success.

To the east of the main field at Kirkland Lake prospecting has carried favourable geological indications as far as the Quebec boundary and some forty miles or more into that Province, where prospectors have been very busy during the present season.

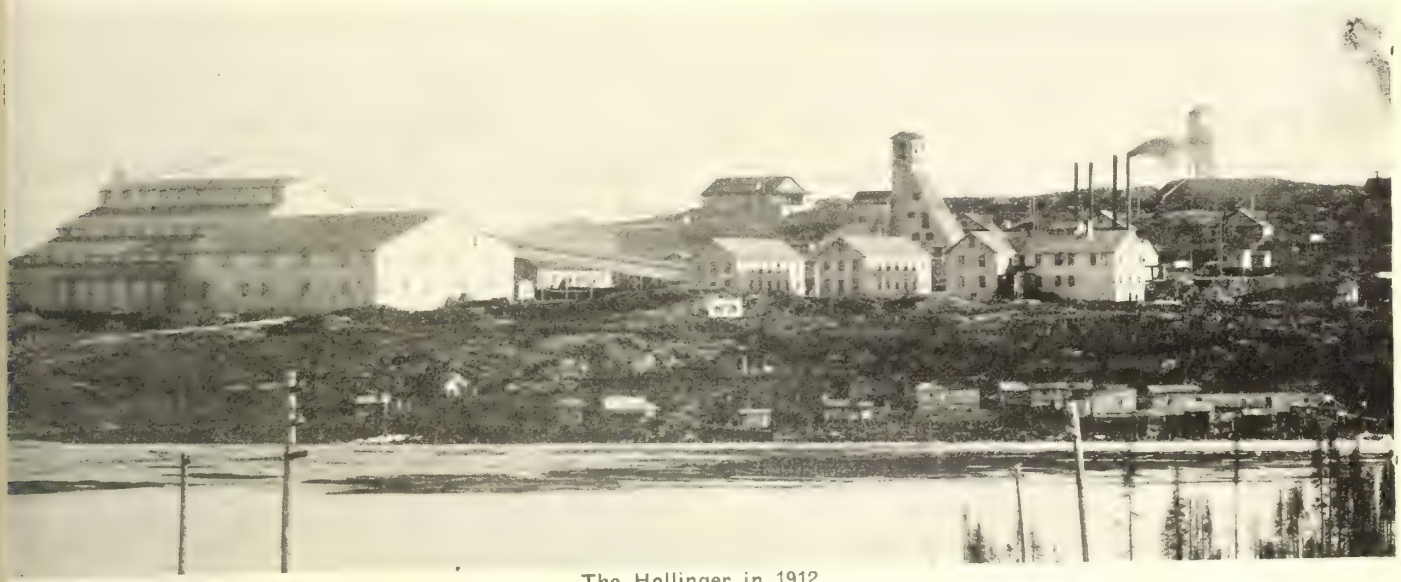
Numerous discoveries of gold have been made in other parts of Northern and Northwestern Ontario. At Night Hawk lake, the Peninsular mine has developed a large body of workable ore and is erecting a mill. The Argonaut mine at Beaverhouse lake, the Associated Goldfields and Crown Reserve at Pancake lake, the Goldale in the Porcupine area, and the Goudreau on the Algoma Central Railway are all under vigorous development, and expect to be turning out bullion ere long.

The production of gold in Ontario in 1922 amounted to

,000,198 ounces, of which 895,409 ounces were from Porcupine, 104,478 ounces from Kirkland Lake, and 310 ounces from miscellaneous sources.

Nickel and Copper

The story of the discovery of nickel in Ontario has also an element of the romantic. What appeared to be large bodies of copper ore were found near Sudbury in 1883 during the construction of the Canadian Pacific Railway. On some shipments of the ore being put through the smelting works at Constable Hook, N. J., the process was attended with great difficulty. On examination it was found that the rebellious element was nickel, and that the mines at Copper Cliff were in reality nickel rather than copper mines.



The Hollinger in 1912

The opening of the deposits synchronized with the notable discovery of James Riley in Glasgow, namely that 3 per cent. of nickel added to steel greatly improved its quality. One of the first applications of this discovery was to the manufacture of armour plates for war vessels. Surface-hardened nickel steel plates proved far superior in power of resistance to any armour plates previously known, and were quickly adopted by the United States navy, and subsequently by the navies of France and Great Britain.

The superiority of nickel steel and the usefulness of the metal for other purposes lead to the establishment of the large industry which now centres at Copper Cliff, Coniston and Nickelton, in the Sudbury area. Nickel being pre-eminently a war metal, the peak of production was reached in 1918, when 1,559,892 tons of ore were smelted and 45,886 tons of nickel produced. The International Nickel Company of Canada is the largest producer, followed by the Mond Nickel Company, and the British America Nickel Corporation. The ore contains an average of 3 per cent. nickel and 1 per cent. copper, and each company has its own method of refining. The Orford process is employed by the International, the Mond er, followed by the Mond Nickel Company, and the Brit- or carbonyl by the Mond, and the Hybinette or electrolitic by the British America.

The close of the war left the companies with large stocks of nickel on their hands, and the high costs during the subsequent period of inflation obliged them to close down or greatly curtail operations. These stocks have now been largely absorbed, and the nickel mining industry is reviving with the prospect of speedily reaching at least the pre-war scale of production.

The foregoing deals only with the four chief metals of Ontario, but the list of the Province's useful minerals is by no means exhausted by mention of iron, silver, gold, and nickel. In truth, the catalogue of the commercial minerals of Ontario is a long and varied one. A number of the minor products provide the basis for important industries. Among these are talc, mica, graphite, feldspar, salt, natural gas, etc., in addition to the more prosaic but not less useful products such as brick, building stone, cement, lime and materials of construction generally. It is a fortunate circumstance that Ontario possesses in great abundance the requisite materials for the substantial and comfortable dwelling houses and structures generally that her northern climate demands.

The Hollinger Today

Geology of Northeastern Ontario

With Notes on Advances in Mining

By WILLET G. MILLER

It is now sixteen years since the mining men of Ontario had the pleasure of a visit from the American Institute of Mining and Metallurgical Engineers. At the time of that visit, 1907, the Province was already noted for its deposits of nickel-copper ores and for those of silver. Since then gold mining has had a wonderful development in the northeastern region, which is now commonly spoken of as the Sudbury-Cobalt-Porcupine region.

A few of those who came in 1907 are to be on the forthcoming excursion. They will note vast changes in the Sudbury area. New plants have been erected, of the most modern type, and large quantities of ore have been developed. During the Great War many users of nickel steel and other alloys of the metal became acquainted with their good qualities. This has resulted in a greatly increased demand for these materials in the arts of peace, and the present activity in the mines and smelters augurs well for the future.

When the Institute excursionists visited Cobalt in 1907 the camp was a little over three years old. They could be shown marvellous outcroppings of ore, and underground, the mines, to use a term that was often employed, were "jewelry shops." Dr. Raymond, the veteran secretary of the Institute, went underground at La Rose mine and expressed his pleasure at the opportunity of seeing the rich veins there exposed. He, or it may have been some other member of the party, advised the young ladies to stand on some of the rich surface outcrops — it would bring them good luck and they "would live happy ever after." This may have been an old Saxon belief, imbibed by the Doctor during his student days abroad!

Now, conditions are changed. Very little rich ore is to be seen at Cobalt. The mills are working on lower-grade material, and have developed processes that are of great interest to the technical man. A paper, by Messrs. Reid, Denny and Hutchison, descriptive of these processes, has just been published and will be distributed during the excursion.

While the spectacular showings of Cobalt are gone, certain outlying cobalt-silver areas give great promise. The excursionists will visit South Lorrain, about fifteen miles to the southeast of Cobalt, where showings of silver ore as rich as those of the mother camp in her palmy days will be seen. There will be other discoveries made in Cobalt itself, and the outlying areas, scattered over a region more than 5,000 square miles in extent, will attract the prospector and the miner for many years to come.

About the time of the last visit of the Institute, or a little earlier, prospectors trained in the Cobalt field began to examine the country farther to the north and northwest. The result has been the development of the gold mines at Porcupine, Kirkland lake and other areas which have attracted world wide attention. The gold production of these areas is referred to in a following paragraph.

During this visit, then, the excursionists will have the opportunity of seeing not only the nickel-copper and silver areas but those of gold as well, a unique triumvirate.

Many promising areas await development. Judging the future by the past, should we not be optimistic?

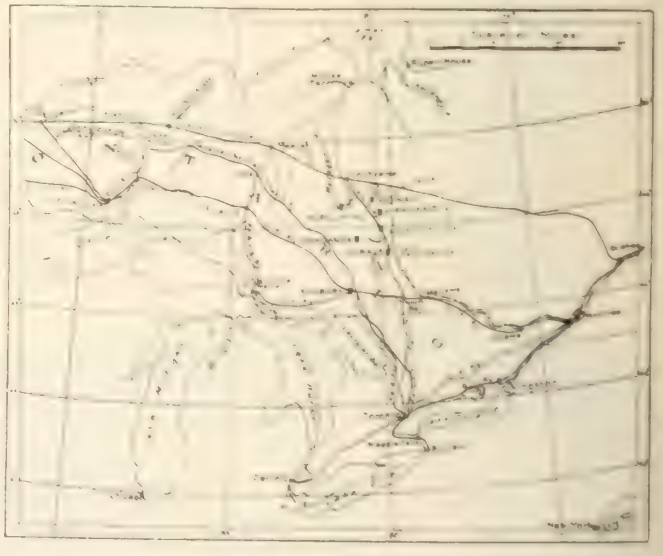
Production

The total production of nickel from the mines of the Sudbury area from 1889 to the end of 1922 was approximately 443,067 tons of 2,000 pounds. The statistics for copper from the area cover a longer period, 1886 to the end of 1922, during which time approximately 259,890 tons of the metal were produced. Platinum, palladium and related metals form interesting by-products of the Sudbury mines, but the statistics are incomplete. From 1904 to the end of 1922, about 331,733,479 ounces of silver have been obtained from the mines of the Cobalt and adjacent areas. A large quantity of cobalt and arsenic have also been produced, together with lesser quantities of nickel and copper. Owing to the fact that the mines did not always receive pay for certain of these metals, which were sometimes lost in treating the ores, it is not possible to give accurate statistics as to production. The value of the gold produced at Porcupine, between 1911 and the end of 1922, amounted to $96,338,114. Between 1913 and the end of 1922, gold to the value of $7,673,966 was obtained from the Kirkland Lake area.

The ore deposits of all three of the areas are in rocks that are classified as of pre-Cambrian age, and are believed to owe their origin to igneous intrusions. At Sudbury the intrusive rock, described on the following pages, is quartz-norite, at Cobalt quartz-diabase, and at Porcupine quartz-porphyry. It is believed that the norite of the one area and the quartz-diabase of the other are genetically connected.

Canadian pre-Cambrian

About two-thirds of Canada is underlain by rock of pre-Cambrian age. There is a similarity in the rocks everywhere. In some areas, of course, certain rocks occur in large volume while others are absent or are found only in small outcrops, and vice-versa. Owing



A large part of Northern Ontario is accessible by railway, as indicated above

to the great mining development in northeastern Ontario, the character and age relations of the pre-Cambrian rocks have been worked out in greater detail here than elsewhere in the Dominion. The following description gives the character of the chief groups in the region:

Relations of Rocks of Northeastern Ontario

Keewatin. — The oldest series known in the region is called the Keewatin. It consists for the greater part of basic volcanic rocks, now represented by schists and greenstones, together with more acid varieties such as quartz-porphyry. Associated with the Keewatin is considerable sedimentary material, consisting of schistose greywacké, jaspilyte, or iron formation, and crystalline limestone, which is, however, not seen in large exposures in any of the three mining areas. These sedimentary rocks are believed to represent the Grenville series of southeastern Ontario.

There are large areas of mineral-bearing rocks of the Keewatin, Timiskaming, Cobalt, Animikie and other series in the pre-Cambrian, which here is undifferentiated

Laurentian Granite and Gneiss. — The rocks next younger than the Keewatin are granite and gneiss. That there were granites older than the Timiskaming sediments is proved by the fact that the conglomerates of the latter frequently contain pebbles and boulders of a light-coloured or grey variety of these rocks. There is doubt, however, about the true nature of certain unconformities that have been described between the Timiskaming and the so-called Laurentian in part of the region dealt with in this article.

Timiskaming. — After the intrusion of the Laurentian into the Keewatin, there was a prolonged period of erosion, during which a thick series of sediments consisting of conglomerate, greywacké and other rocks was deposited. To this series in the Cobalt and Porcupine areas the name Timiskaming has been given. It is known in other areas to the north, south and west of Cobalt and appears to be represented at Sudbury by what Dr. Coleman has called the Sudbury series.

Algoman (Lorrain) Granite. — After the deposition of the Timiskaming sediments an intrusion of granite, characteristically pink in colour, took place. This granite, which occupies large areas, is known as Algoman. The relations of this granite to both the older and younger rocks are clearly shown at Cobalt. The granite, with associated quartz-porphyry, that gave rise to the gold deposits at Porcupine appears to be of the same age.

Cobalt Series. — The period of erosion that succeeded the intrusion of the Algoman granite gave rise to the conglomerate and other rocks known as the Cobalt series. Good exposures of these rocks are to be seen at Cobalt and along the railway to the south and to the north. At Porcupine only small exposures are found. The Ramsay Lake conglomerate of Sudbury appears to be of the same age.

In the Sudbury area there are also other sediments that have been variously classified as regards their age relations.

Nipissing Diabase and Sudbury Norite.—Succeeding the deposition of the Cobalt series came the intrusion of the quartz-diabase which gave rise to the silver deposits of Cobalt. This intrusive is known as the Nipissing diabase. As stated above, the Sudbury norite, with which are genetically connected the nickel-copper deposits, is similar in chemical composition and appears to be of the same age.

Paleozoic Rocks. — To the north and east of Cobalt limestone, with basal conglomerate and sandstone, of Paleozoic age, occurs as outliers on the pre-Cambrian.

With the exception of deposits of glacial and recent age, no rocks younger than the pre-Cambrian are found in the vicinity of Sudbury or Porcupine.

Newer Mining Areas

Kirkland Lake.—The Porcupine area is described by Mr. Burrows elsewhere in these pages. The Kirkland area has now become an important gold producer. The assemblage of rocks is similar to that at Porcupine but gold occurs under somewhat different conditions. Intruding the Timiskaming sediments are various stocks, dikes and sills and Algoman syenite, lamprophyre, feldspar-porphyry and felsite, different facies of one magma intruded in the order of decreasing basicity. The cooling of the intrusive magma was probably accompanied by much shrinkage and faulting along east-west zones in the porphyry and adjacent rocks in planes roughly parallel to the long axes of the intrusions. Through these fractures were deposited the gold-bearing silicious solutions representing the end product of the Algoman intrusions. Porphyry and syenite are the most abundant rocks along the main shear and most of the ore deposits are in these rocks; however, ore occurs in all the other rocks along the path of the shear, with the exception of two diabase dikes which are later than the ore bodies and may be of Keweenawan age. Ore is rarely found in lamprophyre.

The ore occurs at frequent intervals along one major fracture 2¼ miles in length with a strike of N. 70° E, and a dip of from 89° to 85° to the south, occasionally flattening to 50°. The mines, which adjoin one another along this main shearing from west to east are as follows: Kirkland Lake, Teck-Hughes, Lake Shore, Wright-Hargreaves, Sylvanite and Tough-Oakes. In addition to the main fracture there are important branch veins and parallel fractures in a zone 500 feet or more in width.

The four mines in the western half of the area have followed the main zone almost continuously by underground workings for 1½ miles. In the eastern part of the area the vein-bearing zone is over half a mile in width; the main ore-bearing fracture has not been definitely recognized in this eastern section owing to the irregularities of the veins, faulting, drift overburden and insufficient underground work.

The main fracture zone contains two prominent fault planes, called footwall and hanging-wall, which are from a few feet to 40 feet or more apart, the area between being much disturbed with minor faults and slips. The ore occurs over the whole width between the principal faults or near one wall or the other and, in places, beyond the recognizable fault planes or co-called vein boundaries.

The ore at all the mines along the main shear is identical, and occurs as irregular shoots from 30 feet to several hundreds of feet in length, separated by zones of somewhat similar-looking material which may be barren or low in grade. The richer type of ore usually contains lenses of bluish brecciated quartz, the fractures being filled with varying quantities of calcite, dark quartz, dolomite, chlorite, sericite, iron pyrites, gold tellurides, molybdenite, chalcopyrite and, occasionally, some galena, zinc blende and graphite. Frequently the quantity of quartz in the ore deposit becomes relatively small, probably two per cent as compared with the red mineralized porphyry. Again, minute cracks carrying molybdenite, gold, tellurides and a little quartz, extend through the silicified fractured red porphyry, giving a good mill-rock.

The ore minerals are native gold, with the tellurides calaverite ($Au\ Te_2$), kalgoorlite (a telluride of gold, silver and mercury), and petzite ($2\ Ag_3\ Au\ Te$). Other tellurides present are altaite (Pb Te), which is the most common and usually indicates high-grade since it is always accompanied by visible gold; coloradorite (Hg Te); melonite ($Ni\ Te_3$); a sixth telluride was identified by E. Thomson. The minerals present in the ores suggest that they are not high temperature deposits, but that they were formed at considerable depth and exposed by erosion.

The six mines, three of which are from 1,000 to 1,150 feet deep, are developing one vein or lode system, having a total length of 2¼ miles.

Lake Shore Mine
Ten Years Ago

The foregoing description of the Kirkland Lake Area is from a manuscript report by Mr. P. E. Hopkins.

South Lorrain. — The following notes on this area are taken from a report, now in press, by Mr. Cyril W Knight.

Silver was discovered in 1907 at the Keeley mine, and there followed a period of widespread staking of claims, and of active work lasting until the latter part of the year 1913. During this time, which may be called the first period in the history of the camp, there were produced about 2,500,000 ounces of silver practically all of which came from the Wettlaufer. The camp then became almost inactive for eight years. In 1921 rich ore-shoots were discovered and South Lorrain thereupon entered the second period of its history, and now gives promise of developing, for the time being at least, into the most important of the outlying cobalt-silver areas.

The geology of South Lorrain is similar to that of Cobalt. The productive veins occur along the top of the Nipissing diabase sill, both in the diabase and in the overlying Keewatin. In this respect the occurrence is

similar to that at the Timiskaming and Beaver mines in Cobalt. The diabase sill in South Lorrain has the form of a great elongated dome. The productive veins discovered up to the present have been found on the northwest slope of this dome. A feature of the veins is the depth to which pre-glacial weathering has extended. In the Wood's vein, the depth is at least 480 feet . To show the richness of the ore it may be said that a shoot of ore on Wood's vein 102 feet long, with an average height of 35 feet, had produced 900,000 ounces of silver to the end of April, 1923. Detailed descriptions of the geology and mining opertaions are given in Mr. Knight's report.

Other Areas. — Important mining development is taking place in other areas in northeastern Ontario. The names of most of these areas, and their location, are shown on the accompanying sketch maps of the silver and gold regions.

PERSONAL AND GENERAL

Hon. Robert Drummond of Stellarton, Nova Scotia, veteran editor of the *Maritime Mining Record*, spent a few days in Sydney recently. His friends there were delighted to find him in perfect health, as usual, and enjoyed the annual treat of his sparkling humour and pleasant greetings.

Mr. John Taylor, of John Taylor & Sons, London, will visit Kirkland Lake, where his firm has large commitments, undertaken by their Canadian representative, Mr. A. D. Miles. John Taylor & Sons own and manage a large number of well-known mines throughout the world, most of them in various parts of the British Empire. Among them are the Cape Copper Company, Balaghat Gold Mines, Ooregum Gold Mining Co. of India, Mysore Gold Mining Co., Mount Boppy (Australia), Cordoba Copper Co. (India), Champion Gold Reef Mines of India, etc.

Mr. Robert Henderson, Mine Manager, Reserve Mine, Western Fuel Corporation, has resumed his duties after a short vacation. Mr. A. Newbury acted as Mine Manager during Mr. Henderson's absence, and now is acting as Mine Manager of No. 1 Mine during the absence of Mr. Robert Laird, who is away on holiday.

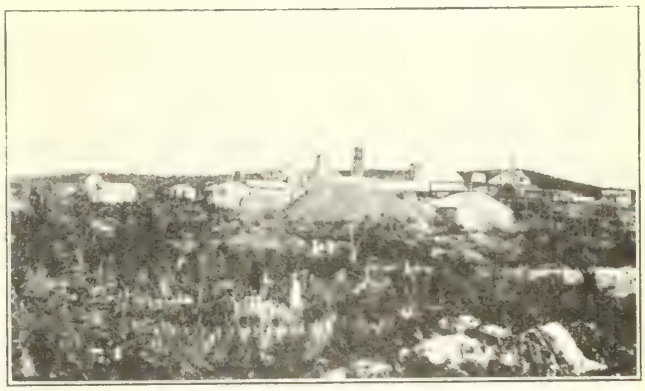
Mr. Morris W. Garman has been appointed Mine Manager of Granby No. 1, operated by the Granby Consolidated M. S. & P. Co., in place of Mr. J. B. Touhey who is on vacation.

Mr. James Dickson, inspector of mines and member of the Board of Examiners of British Columbia, is away on vacation.

Mr. D. H. McLean of Glace Bay, Nova Scotia, assistant to the General Superintendent of Mines, Mr. A. S. McNeil, and Mr. Lionel Frizzel, Chief Electrician of the Dominion Coal Company, are enjoying a well earned holiday subsequent to the strenuous duties of the strike period.

Sir Newton Moore has returned from a visit to the Wabana iron ore mines, where he inspected mines and plants. He left Sydney last week for New Glasgow and from there will go on to Halifax in company with Mr. D. H. McDougall, vice-president of the British Empire Steel Corporation. Sir Newton is an Australian with a long record of public service, including the premiership of W. Australia. Early in life he became interested in military affairs, and during the Great War commanded the Australian military forces in England. He is a director of numerous mining companies throughout the world, including the British Empire Steel Corporation, Hampton Gold Mining Areas (Australia), British Porcupine Development Company, and California Exploration Company.

Mr. H. S. Munroe, general manager of the Granby Consolidated M. S. & P. Co., has been elected a vice-president of the Company.



Vipond Mine and Mill, Porcupine

REPORT ON SILICA DEPOSITS OF EASTERN CANADA

Silica, in the form of quartz, quartzite, sandstone, sand, etc., has been utilized for many years in numerous manufacturing industries. It is widely distributed in nature and is found in all degrees of purity. In the form of sand it is employed in the manufacture of glass, carborundum, and in the steel foundries. In lump form it enters into the manufacture of ferro-silicon, and is also used as a flux in metallurgical operations. When finely pulverized it is used in pottery bodies, and also in the enameling and paint industries.

A report on Silica by L. Heber Cole, recently published by the Mines Branch, Department of Mines, Ottawa, discusses the occurrence, exploitation, and the uses of this product and describes in some detail the many occurrences of this material in Eastern Canada, including many undeveloped deposits that may in the future become of considerable industrial importance.

The principal markets for silica are located in the large industrial centres of the country, such as Montreal, Toronto, Hamilton, etc There are many deposits favourably situated in the provinces of Ontario and Quebec, which if properly operated should be able to compete readily with similar material which at present is being imported from the United States.

This report on Silica, which comprises 199 pages of text, is profusely illustrated with diagrams and photos and is accompanied by a complete set of maps showing the distribution of silica deposits. It may be obtained by application to the Director, Mines Branch, Department of Mines, Ottawa.

PHOSPHATE SHIPMENTS

Shipments of phosphate from the large deposits recently opened up in Morocco are now assuming important proportions. During the first six months of 1923, shipments were 84,000 tons, against 82,000 tons for the whole of 1922

A Short Summary of the Mining Act of Ontario

By T. E. GODSON, K. C.*

The present Mining Act of Ontario may be briefly outlined as follows:—

Staking. — Anyone over eighteen years of age who takes out a Miner's License, at the cost of five dollars, may prospect for minerals upon Crown Lands or lands of which the mining rights are reserved to the Crown, and may take up, work and acquire title to a specified area, by staking out and recording a Claim, performing and filing proof of the prescribed development work, namely, two hundred days, obtaining a survey, if in unsurveyed territory, and paying $3.00 per acre in surveyed territory, and $2.50 in unsurveyed territory, patent being given in fee simple upon completion of these requirements.

Claim Tax. — After patent or lease issues from the Crown, the Claim is subject to a tax of five cents per acre, payable annually. If default is made for two years the land may be forfeited to the Crown, pursuant to the provisions of the Mining Tax Act.

Transfers. — The Claim or any share or an interest in it, may at any time be sold or transferred to any Licensee, and transfers, agreements and other instruments executed by the recorded holder may, and to ensure preservation of priority must, be recorded in the Recording Office, being the depository of title prior to patent, in the same manner as the Registry or Land Titles Office is after patent.

Certificate of Record. — The validity of every Claim is open to dispute for sixty days after recording, and when this time is past, a certificate of record may be obtained, and on satisfactory proof of performance of work a certificate of such may also be obtained and these, in the absence of fraud or mistake, are conclusive evidence of performance of the requirements of the Act.

Disputes. — Questions of disputes arising under the Act, either between individuals, or between an individual and the Crown, are adjudicated by the local Recorder or by a special officer called the Mining Commissioner, subject to appeal to the Supreme Court of Ontario.

Safety Regulations. — Rules and regulations are prescribed for the operation of mines (whether on patented or unpatented lands) looking to the safety of employees and the protection of the rights of other miners and for the collection of statistics.

Act is Comprehensive. — Legislation by Order-in-Council is not resorted to, although to a certain extent adopted as of necessity, during the late war. There are no rules and regulations for procedure except those contained in the Act. The comprehensive scope of the Act, and its definiteness of detail, make it lengthy, but give greater certainty and security to the interest of the holder.

Mining Commissioner. — The Mining Act of Ontario is unique, providing a special tribunal presided over by the Mining Commissioner, for the trial of all questions and disputes arising before or after patent as to the validity or subsistence of a patented or unpatented Mining Claim, or as to its transfer or ownership, or as to any other rights or privileges, or interests conferred by the Act, subject to appeal to the Supreme Court of Ontario.

The position of Mining Commissioner is the equivalent of that of a Judge, and the procedure leading to trial is simple and expeditious. All matters are brought to a hearing by obtaining and serving an appointment after dispute of notice of claim has been properly filed, and the issue is heard, if possible, within the Mining Division where the land is situated. All decisions must be entered in writing and the parties affected notified by registered mail. An appeal to the Supreme Court of Ontario is allowed in most cases, if taken within fifteen days after decision rendered and filed.

Forfeiture. — Rights or interests in a Mining Claim become automatically forfeited to the Crown on the non-performance of the requirements of the Act relating to the (a) taking out of a License; (b) performance of work; (c) filing of work; (d) application for patent. These forfeitures may be relieved against upon terms, if application is made to the Mining Commissioner within three months after the loss of rights arises, or at any time under a general relieving section (86), if the facts and circumstances warrant. All applications for relief from forfeiture, if adverse interests have arisen, are heard and disposed of in open Court and upon notice to all interested parties. These curative sections make the Act more elastic and pliable.

Rights and Easements. — Another salutary provision of the Mining Act is that which has reference to rights and easements required for or in connection with proper working of the mine or mill for treating ore or quarry. The owner, lessee or holder or person entitled to work the same, may obtain and have vested in him by Order or award of the Commissioner, made after hearing such parties interested as may appear, or on appeal from him, the right to construct ditches and flumes, to discharge, drain or divert waters, and to store and take water, establish rights-of-way through or over any land or water, or roads, tramways, etc., for the transmission of electricity, and for the depositing of tailings, slime or other waste products upon the land of another owner. No such right shall be granted unless all injury or damage caused to any other person thereby can be adequately compensated for, nor unless in all the circumstances it seems reasonable and fitting to grant the same, and in the exercise of that right so granted no unnecessary injury or damage shall be done to the land, property, or rights or interests of other persons, and all injury and damage which may be caused to any person by the granting and exercise of any right obtained under this Section shall be fully compensated for. There is a right of appeal from the decision of the Commissioner under this Section. It is found that the Section is a very desirable one and in most cases the right asked or remedy sought for is usually arranged amicably after the matter has been aired before the Commissioner.

*Mining Commissioner for Ontario.

Mines Inspection in Ontario

By T. E. SUTHERLAND*

Regulations regarding the protection of workmen and the safe operation of mines form an important part of the mining laws of Ontario. The enforcement of these regulations is the duty of the mine inspectors, whose powers and duties are governed by statute.

In a general way it may be said that these regulations are based on the South African Act and on the "Rules and Regulations for Metal Mines" published by the United States Bureau of Mines as Bulletin 75. Bulletin 75 gave the findings of a committee comprising W. R. Ingalls, James Douglas, J. R. Findlay, J. Park Channing and John Hays Hammond, who on the invitation of Dr. Holmes, Director of the United States Bureau of Mines, served as a committee of the United States Bureau of Mines, their object being to draft a uniform mining law for the States of the Union.

Besides the copper-nickel mines at Sudbury, the silver mines at Cobalt and the gold mines of Porcupine and Kirkland Lake, Ontario has a great variety of mines, including barite, feldspar, fluorspar, granet, graphite, gypsum, hematite, iron pyrites, lead, mica, molybdenite, siderite, sodalite and talc. Included as mines for purposes of administration are all quarries, clay pits and sand and gravel pits in the Province.

Powers of Inspectors

The difficulties of drafting legislation that would properly safeguard large operations, and at the same time not ask for absurd observances at small properties, can readily be understood. In order to avoid these difficulties, unusual powers are given to the inspectors. The enforcement of the regulations is necessary only where in the opinion of the inspector they are "reasonably applicable", and a further blanket clause is added giving the inspector power to take any steps he may deem necessary to protect the health or safety of the workmen. Furthermore the decision of the inspector is not subject to review by any other officer of the Department. The inspectors are appointed by the Crown and can only be removed for cause. In the appointment of an inspector two requirements are insisted upon, — that he be a graduate in Mining Engineering of a Canadian University and that he have 5 years' experience in actual mining operations. As an example of the satisfactory way in which this system has worked out it may be mentioned that the abolition of dry stopers underground was accomplished through the coöperation of the mine managers and that no special legislation was necessary.

Character of Regulations

The regulations cover the usual requirements for safe mining practice, such as ventilation, handling and storage of explosives, haulage, scaling, hoisting, and electrical installations. An electrical inspector looks after the last. With a temperature ranging from 100°F. in summer to 50° F. below in winter the storage, handling and thawing of explosives is a serious problem. When we realize that one Ontario mine uses 3,000,000 lbs. of nitro-glycerine explosives yearly, the magnitude of this task can be appreciated.

Ontario mining laws have one requirement which I do not believe is asked for in any state of the Union, that is, that hoisting ropes be regularly subjected to a breaking test. For this purpose the Government have installed at Toronto a Tinius Olsen 300,000-lb capacity, 4-screw type testing machine with automatic beam and speed regulated cones and Bristol recording chart, showing extension and pull. A nominal charge is made for these tests. Some of the rope manufacturers are making use of this machine.

Penalties for non-observance of the mining regulations are provided for. These range from $10. to $100. for workmen, and $100. to $1,000. for companies. During 1922 seven prosecutions were made, three being against workmen and four against companies. The Department has not yet lost any action instituted against a company or a workman.

In 1922, 1,320 inspections were made, 1,133 works were visited, and 2,689 instructions were given regarding unsafe conditions or practices. Approximately 12,000 men were employed during the year at the mines. The accident rate worked out at about 110 non-fatal and 2.5 fatal per thousand men employed. Inquests are held and attended by an inspector in the case of all fatal accidents.

Workmen's Compensation Rates

The assessment per $100 of pay roll made by the Workmen's Compensation Board is based on the actual cost of the accidents occurring in each class during the previous year, and consequently shows the accident hazard of each class. The adjusted rate for 1921 and the provisional rate for 1922 were as follows:

	1921 Adjusted	1922 Provisional
Silver Mining	$2.25	2.25
Treatment of ores, with heat, in a silver mining industry	1.10	1.10
Treatment of ores, without heat, in a silver mining industry	.60	.60
Gold mining	2.40	2.40
Treatment of ores, with heat, in a gold mining industry	1.20	1.20
Treatment of ores, without heat, in a gold mining industry	.60	.60
Nickel or nickel-copper mining	2.75	2.75
Treatment of ores, with heat, in a nickel or nickel-copper mining industry	1.40	1.40
Treatment of ores, without heat, in a nickel or nickel-copper mining industry	.60	.60
Mining N. O. S.	2.25	2.25
Treatment of ores or minerals, with heat, in an industry in this group	1.10	1.10
Treatment of ores or minerals, without heat, in an industry in this group	.60	.60
Iron smelting, as a business	2.00	2.00
Treatment of ores or minerals, with heat, N. O. S. as a business	2.00	2.00
Treatment of ores or minerals, without heat, N. O. S. as a business	.60	.60
Refining of nickel, as a business	2.00	2.00
Sand, shale, clay or gravel pits	3.00	3.50
Quarries, as a business; stone crushing	6.00	[illegible]

* Chief Inspector, Dept. of Mines, Toronto.

It will be noted that the Workmen's Compensation rates show a very high hazard for quarry work compared with mining. Quarry operations being carried on above ground, in daylight only, with plenty of room and principally during the summer months, one would expect fewer accidents compared with underground operations. The casual type of labor employed and less efficient management are, I believe, the causes for the higher accident rate.

It may be safely said that the accident rate depends more on the mental attitude of the management towards accidents than on mine inspection. Ontario mines are exceptionally safe to work in, standard mining methods only are used, the equipment is all that could be desired, there is a good class of labor, 66 per cent, being English, Canadian or American, and the management is efficient.

ONTARIO'S ADVANTAGES AS A MINING COUNTRY

by T. F. SUTHERLAND

1. **Location.** — The mining districts of Northern Ontario are nearest to the financial and industrial centres of Canada and the United States. The distances from Toronto are as follows: Sudbury, 260 miles; Cobalt, 331 miles; Kirkland Lake 392 miles; and Porcupine, 482 miles. Toronto is 565 miles from New York City.

2. **Accessibility.** — Pullman trains run into all the camps; there are express, telegraph, local and long distance telephone service and motor roads in every camp.

3. **Climate.** — It has the advantage of the climate of the North Temperate zone, with an elevation not over 1,000 feet above sea level. It is one of the healthiest climates anywhere in the world.

4. **Government.** — It has an eminently stable form of government. Its inhabitants are an English speaking, self-governing, law-abiding people.

5. **Mining Laws.** — The Ontario Mining Act is considered one of the best. Lands, minerals, etc. belong to the Province and are granted in fee simple; title is unassailable. There is a special official with judicial powers and title of "Mining Commissioner" who settles all disputes among prospectors and others in local centres.

6. **Taxation.** — Taxes are levied only on profits. A 3 per cent yearly tax is due on all profits over $10,000. and up to a million, and 5 per cent on all profits over a million. Part of this amount is returned to the municipality for local purposes. Profits are determined by the "Mine Assessor", a special official appointed by the Crown.

7. **Power.** — An abundance of hydro-electric power is developed by independent companies and delivered to the mines at reasonable rates.

8. **Timber and Water.** — It is a well watered and well wooded country; timber and water for mining and treatment purposes are abundant in every district.

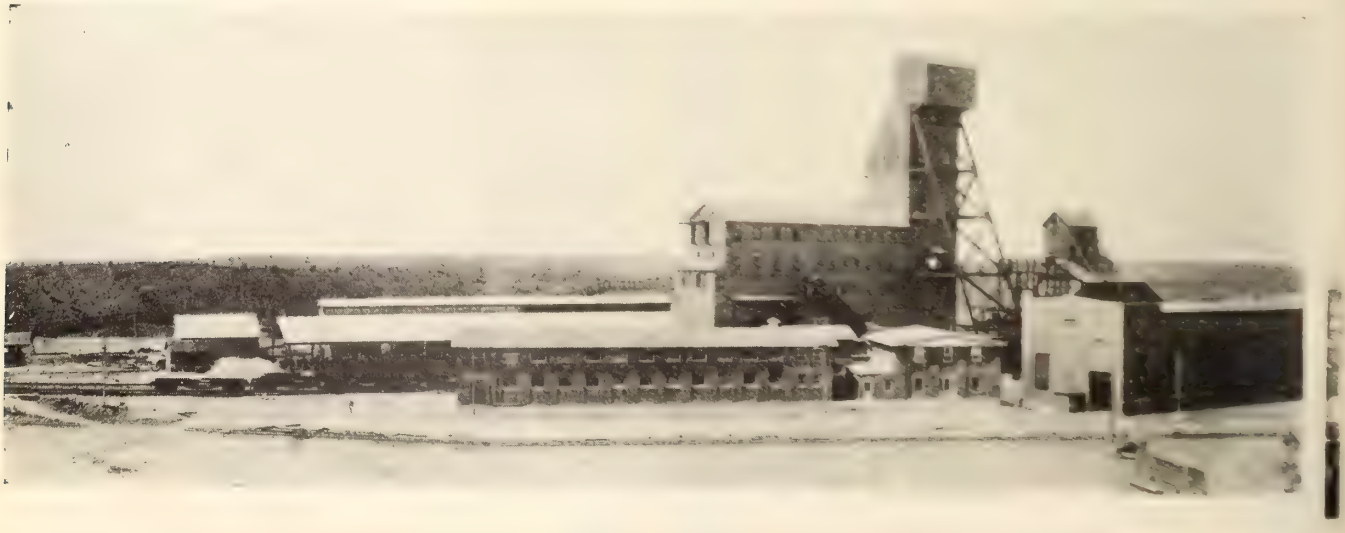
9. **Ore Extraction Problems.** — There are none. The ore-bodies are regular, enclosed in rocks that give self-supporting walls. Caving ground, swelling ground, high temperatures, gaseous mines, dusty mines, big flows of water, none of these conditions exists.

10. **Labour.** — There is a plentiful supply of good labour. A majority of the labour is English-speaking. The climate is conducive to physical activity, and the miners are a steady, dependable lot.

11. **Profits.** — This is the supreme test. Cobalt to the end of 1922 produced $221,000,000 and paid out in dividends $94,000,000 or 42½ per cent. Porcupine to the end of 1922 produced $108,000,000, and paid out as dividends $28,000,000 or nearly 26 per cent. Complete figures for Sudbury are not available, but for the years 1911 to 1915 inclusive the profits were almost $10. on every ton of ore treated.

12. **Future Possibilities.** — A large portion of the Province, geologically favourable to the occurrence of ore deposits, has not been prospected. Much of the area prospected has wonderful future possibilities owing to increased geological knowledge. In the past two years, ten properties in the gold belt that now may be called mines have been developed on mining lands taken up prior to 1909.

Conclusion. — Compare Ontario with other mining countries. — Mexico, Australia, Africa, India. All have certain advantages, but none have all the advantages that Ontario possesses.



Creighton Mine

Sudbury --- Ontario's First Mining Camp

Its Influence on the Province's Mining Industry

BY T. F. SUTHERLAND*

The first mining of any importance in Ontario was at the Bruce Mines on the north shore of Lake Huron in 1846, when an English company mined the copper-quartz veins of this district, making a concentrate that was shipped to England. These operations showed a profit for many years, but ceased in 1875. It cannot be said however, that they had any marked effect as regards the establishment in this province of a successful mining industry, and it was the discovery of the Sudbury deposits during the construction of the C. P. R. in 1883 that was destined to prove to the world that the northern part of this province is a storehouse of mineral wealth. Few people, possibly, realize the effect that this discovery had in the advancement of the province as a whole. Progress was slow at first, for two reasons: first, the metallurgical processes for the recovery of nickel had to be developed from the very beginning, and secondly, the value of the new industrial metal, nickel, had to be demonstrated and a market found for it.

Early Development

Government surveyors laying out base lines for townships first drew attention to mineralization in this district. Salter in 1856 reported that while surveying a meridian north from Whitefish lake he noticed considerable local attraction between the 5th and 8th mile, and at 43 chains north of mile post VI there was "an appearance of iron in trap." This was within two hundred yards of the Creighton mine, which afterwards developed into the world's greatest nickel mine and gained the distinction during the high metal prices of the war of being the largest high-grade mine in the world, or the highest-grade large mine. Railway navvies blasting out an iron-stained rock carrying copper pyrites in a cut four miles west of Sudbury during the construction of the C. P. R. in 1883, where now the Murray mine is, noticed the second indication of Sudbury's nickel wealth, and some of the pioneers, always ready to take a chance, began to apply to the Government for the gossan ridges of this timbered country as mining claims. Copper ore was shipped out in 1887, and then the real troubles of the pioneers began. Difficulties in treating these copper ores were experienced and a chemist for the Orford company found these were due to nickel.

From that day to the present the success of the industry has depended on the research chemist. The first problem was how to separate the nickel. Then uses for the enormous quantities available had to be developed. The metallurgy of nickel was worked out by the two large companies and each evolved a process of refining distinct in practice, the Orford process an adaptation of English methods, and the Mond process a brand-new one based on laboratory experiments. The Norwegians worked out a third refining process, the Hybinette, which is now used by the third Sudbury company. The smelting processes are the same.

From 1900 up to the time of the World War the growth was gradual, with an increase in production of about 10 per cent. a year. Then during the war the companies had a market for all the nickel they could make. Following the war the research chemists came back into prominence as the saviours of the industry. Commercial uses had to be found for immense quantities of nickel which the mines, smelters and refineries were prepared to turn out. In this they have been so successful that today the production is equal to pre-war figures and the industrial uses are still increasing. We thus see that the discovery of nickel at Sudbury developed research chemists who, besides making the mining industry in this district successful, have added enormously to the industrial life of the nation.

Mining Methods

The nature of the ore-bodies and the character of the enclosing rocks did not necessitate any marked variation from accepted mining practices. However, the tonnages hoisted in later years were large and the problem of changing over from low tonnage to high tonnage mines, and equipping the mines underground and on the surface to handle economically these large tonnages, developed engineers whose successful results in the Sudbury district have been copied

*Chief Inspector of Mines, Toronto.

Smelter of the International Nickel Company at Copper Cliff.

in other mining districts of Ontario. Men trained under these engineers are in demand in every mining camp in the north.

Geology

I am not prepared to state what effect, if any, the working out of the geology of the Sudbury district has had on the geological problems of Northern Ontario. As the years rolled by and the enormous ore bodies of Sudbury were developed, as the marvellously rich veins of Cobalt continued to produce, as the gold mines of Porcupine and Kirkland Lake increased in area and gold content, and as the geological relationships were worked out, a marked confidence in geologists has been engendered. The value of their science has been proven and one of the outstanding features of the industry in Ontario today is the great amount of geological prospecting that is being carried on. Conservative mining companies are willing to spend as much as $250,000 in a single venture if their geologists will say the formations are favourable.

Mining Development

The success of the two Sudbury companies, one American and one British, with the consequent payment of dividends to American and British investors did an immense amount of good in creating confidence in the possibilities of Ontario as a field for mining investment. The companies, being equipped for mining, smelting, refining and marketing nickel and having problems to solve continually in these departments, did not, as companies, seek for deposits of other metals; but they readily investigated all nickel occurrences. Officials and stockholders were, however, continually investigating the newer camps and investing in them, and are responsible for a considerable amount of the advance made; and today some of the boldest mining programmes in Northern Ontario are financed by money made in Sudbury and directed by technical men who received a large part of their training in the nickel district.

Settlement

The development in a new district of an industry which in 1918, its peak year, produced approximately 46,000 tons of nickel, valued at 26½ million dollars, and over 23,000 tons of copper, and which paid out over $7,000,000 in wages and gave employment to 4,000 men, cannot be otherwise than the foundation of the prosperity of that district. Towns and villages with a population of 20,000 are practically dependent on this industry, and a large farming community owes its prosperity to the high priced market the mines make possible for their product. A great many of these farms are owned by men who at one time were employed by one or other of the companies. There are Finn and French-Canadian communities where every land holder is an ex-miner or smelterman.

Political

Perhaps it would be just as well to touch this phase of the subject a little gingerly. During the war, prior to 1917, the export of nickel from Canada was the subject of a great deal of newspaper criticism. The British-owned company escaped this criticism, as their refinery was in Wales. The American company's refinery was in New Jersey. In spite of assurances from the British and Dominion governments that the export of nickel from the American company was satisfactory to the British Admiralty, the press continued the controversy and political parties made capital out of it. A Nickel Commission was appointed by the Provincial Government to investigate the whole question. The American company built a $5,000,000 refinery in Ontario, which now handles all the matte of their Sudbury plant that is refined. Monel metal is still made from exported matte.

The Nickel-Copper Industry's Record

By ALEXANDER GRAY*

The nickel-copper industry of Ontario may be credited with a metallic output of nickel, copper and rare metals, valued approximately at $241,000,000. This valuation is more or less nominal, and is based upon averages as presented in the year-to-year Provincial reports. To the end of 1922, the grand total value of the metals extracted from the ores of the Sudbury district may be summarized in this way:

Nickel	$176,700,000
Copper	60,800,000
Platinum	3,600,000
	$241,100,000

This grand total is hardly representative of the market valuation of the metals; yet it suffices to demonstrate the achievements of the nickel industry despite adversities. No official statistics on the subject have appeared since 1920 else it would be possible to complete the following wage bill of the nickel industry:

Years	Total Wages	No. of Employees
1908	$2,139,055	2,416
1909	2,605,128	3,251
1910	2,973,172	3,317
1911	1,830,526	2,439
1912	3,543,419	3,736
1913	3,291,956	3,512
1914	3,424,352	3,859
1915	3,835,179	4,538
1916	4,920,720	5,306
1917	6,113,572	3,747
1918	7,983,526	4,378
1919	4,139,523	3,004
1920	6,704,883	4,007
	$53,525,011	

This record dates from the panic of 1907. After the Armistice the nickel industry, beset by the universal industrial depression and subjected to special surtaxes, found the heavy capital expenditures incurred for war purposes called for complete retrenchment. Refineries and smelters, huge plants, were forced into almost complete idleness; staffs were reduced to the minimum; only taxes were maintained; yet the International Nickel Corporation between September 1902 and December 31st 1920 had expended this in its local mining and smelting division:

Labor and Salaries	$35,913,755.32
Mine Supplies	13,915,453.36
Coke	6,485,869.68
Coal	2,439,869.68
Wood	685,578.31
Freights	11,736,230.97
Contractors	2,114,233.77
	$73,190,529.65

* Consulting Mining Engineer, Montreal.

Even though Canadian nickel-copper in the matte went to Bayonne and Clydach, and the credit taken for the industry in its record of output be inadequate, its spending power and constructive influence in the development of the Canadian mineral industry in general, cannot be questioned. Matte still goes to Wales, Pennsylvania and West Virginia, but the nickel-copper industry is now almost completely Canadianized, and in time it may cease to be regarded as an industrial Ishmaelite, denied equal taxation notwithstanding its post-war plight.

If Canada was supersensitive because its war metals were refined abroad, the reason for revenual reprisals has been removed in large measure. The nickel industry during and since the war has expended about $35-000,000 on new plants. Therein has been its weakness and its strength, for it is over-trained for greater outputting, and Dr. Corless has put it on record that there is at least 100,000,000 tons of nickel-copper ore in the ascertained reserves.

The Mond Company has expanded in every direction. The British-America Nickel Corporation cost more than it may be able to surmount although its establishments attain almost complete efficiency. The International Nickel Corporation of Canada and its parent organization, the International Corporation of New Jersey, are ready to meet the world's requirements. Their Port Colborne refinery, which cost about $6,000,000; their Spanish River dam and hydro-electric development that cost about $3,200,000; the Creighton Mine surface equipment, which cost about $1,250,000; besides the extensions to the furnace and converter plants; to say nothing of the three-and-a-half million dollars rolling mill at Huntington, West Virginia, bespeak more of optimism than post-Armistice business warranted.

Granting that the Mond rolling plant in Clearfield, Pennsylvania, and the International mill in West Virginia reflect the altered conditions confronting the nickel industry, and that diversified markets will be created for Monel metal and for multiform nickel products, there is no trepidation among producers, even though there be hesitation on the part of consumers and prohibitive market conditions in Europe. The latest bulletin on the subject issued by the Ontario Department of Mines, had this encouraging view:

Results for First Quarter of 1923

"Production from the Sudbury area is on the increase following the post-war depression. The Mond Company has a plant at Clearfield, Pa., for the production of malleable nickel, and the International Company now operates at Huntington W. Va., a rolling mill for nickel and monel metal products. The industrial uses of nickel are rapidly expanding. In April an announcement was made that mine, smelter and refinery of the British America Nickel Corporation would be soon placed in operation after a prolonged shut down. During the period the Mond and International companies smelted 192,118 tons of ore and produced 10,748 tons of nickel-copper matte. The Mond Company made no shipments, but the International shipped 2,271 tons of matte to Huntington,

W. Va. and 6,234 tons to Port Colborne, Ont. At the latter plant 6,764 tons of matte were treated."

Supplementing these figures are the following for the first quarter of 1923 and 1922:

Products	Quant. (3 mos.) 1923	1922	Val. $ (3 mos.) 1923	1922
Platinum metals, ozs.	20	.....	1,740	....
Copper (metallic), lbs.	2,872,540	22,553	460,441	1,310
Copper in matte exported tons	549	5	109,875	897
Nickel in matte exported tons	1,270	.....	507,836	....
Nickel oxide, lbs	3,140,298	25	451,213	7
Nickel, metallic, lbs.	4,761,768	522,184	927,406	129,055

While the nickel industry is more prosperous, it has reason to be impatient about the restoration of its prestige in its own sphere. Current production compares favorably with pre-war conditions but competition is keen and for a while the market price of nickel was the lowest since 1895. Certainly production costs are better. The quality of Monel metal is superior to what it was, and it has been ascertained that the market for it is capable of large expansion. The Mond plant in Pennsylvania has been rolling sheets and drawing tubes, malleable nickel being the main product. The British America prospects are more hopeful. The rehabilitation of the whole industry is progressing rapidly.

Apart from the increasing output perhaps the most informative data bearing upon what the nickel industry has passed through are contained in the consolidated general profit-and-loss statement of the International Nickel Company of New Jersey for the years 1920, 1921 and 1922:

	1922	1921	1920
†Earnings	$ 373,986	$4,059,607	$6,064,76[illegible]
Oother inc.	234,267	1,106,974	30[illegible],71
Gross inc.	607,353	5,166,581	6,365,47[illegible]

ARCTIC EXPLORATION

A month ago the famous "Arctic" sailed once more to the North, in charge of Mr. J. D. Craig. Captain J. E. Bernier is the skipper. The purposes of the voyage are manifold, including exploration, the provisioning of some Arctic posts, and the administration of justice. The personnel includes surveyors, naturalists and engineers.

NATURAL GAS PRODUCTION

The production of natural gas in Canada has now reaced a position of considerable importance. In 1922 it was 15,000,000 thousand cubic feet, valued at $5,500,000. Alberta, with 5,867,000 thousand cubic feet, is catching up rapidly to Ontario, which retains the lead with 7,800,000 thousand cubic feet. New Brunswick's quota for 1922 was 754,000 thousand cubic feet.

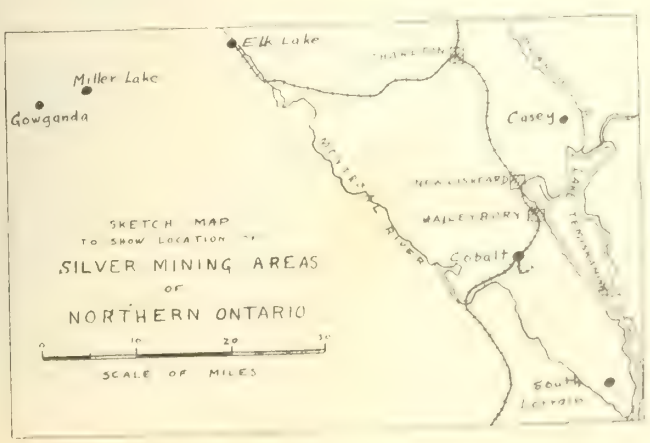
Surface Plant at Coniagas Mine, Cobalt

The Influence of Cobalt on Canadian Mining

By J. MACKINTOSH BELL

The discovery of the extraordinarily rich silver veins of Cobalt marks the real beginning of successful precious metal mining in Ontario. In 1903, when Cobalt's brilliant career began, there was not one prosperous gold mine in operation in all Canada, and silver, except as a by-product or a co-product, was in much the same position as gold. Even the placer fields of the Klondike had passed their zenith.

The bonanzas of the famous Silver Islet Mine in Lake Superior, rich as they were, were not sufficiently extensive to draw very widespread attention to the potential mineral wealth of the pre-Cambrian areas of Ontario, and such interest as was aroused was dissipated by the generally unfavorable results attending the development of the silver-bearing deposits on the Lake Superior mainland. As gold-field after gold-field, — Rainy River, Wabigoon, Michpicoten, and others — came into the limelight, and as each failed to live up to the hopes of the discoverers, popular enthusiasm waned to the vanishing point. Even the most optimistic began to be dubious of Ontario's ever producing a really successful gold or silver mining field.



Probably this succession of disappointments explains why Cobalt failed in the first instance to appeal to an apathetic and suspicious public, notwithstanding the authoritative support the locality early received from Dr. W. G. Miller. The promoter and the broker came, as in the case of the earlier discovered fields; but in this instance there was real foundation for the boom that followed. And the boom at Cobalt had one good effect. It induced widespread prospecting. The first discoveries were soon followed by numerous others within a radius of four or five miles from the original location, while within a few years the subsidiary camps of Elk Lake, Gowganda, South Lorrain, and Casey had been found, with deposits similar to those of Cobalt.

Meanwhile, Cobalt had settled down to the real business of mining and the world awakened to its importance. Canadians were, not unnaturally, the first to become interested, but United States capital was not dilatory in grasping the opportunity of securing holdings in the new camp. English investors, still smarting from the succession of shocks administered by the Rossland and Lake of the Woods fiascos, moved more cautiously; but ultimately even they bought their way in, at prices that might have staggered the original investing pioneers.

The Town of Cobalt in November, 1905

The widespread quest for new Cobalts led to a search for gold as well. Larder Lake was early located, and while the large hopes of its importance were at first doomed to disappointment, the hunt did not cease, and when in 1909, rumors of discoveries of gold in the Porcupine region were current, they were not disbelieved. The stage was better set for action than in 1903. Money in large quantity had been made. The spirit of successful adventure was abroad. The McMartin-Timmins-Dunlap group, — the earliest of the Cobalt pioneers,—had sold their Cobalt property, La Rose. A large part of the purchase price received was forthwith diverted to the purchase and development of the now world-famous Hollinger property. Similarly, interests connected with the International Nickel

Company early acquired the Dome property, and others, identified with the development of the Temiskaming Mine at Cobalt, brought the MacIntyre to success. One has only to recite such names as McMartin, Dunlap, Timmins, Hay, and Drummond, to be reminded how Cobalt gave the impetus to the beginning of Porcupine.

Cobalt had so enlarged the mining vision as to enable the pioneers of Porcupine to undertake, with relative equanimity, expenditure on a scale much larger than was current before the silver eldorado had been discovered. A mental attitude has much to do with mining. It is even conceivable that Porcupine might now be as inactive as the Lake of the Woods district, but for the finding of Cobalt. Gold, indeed, had been discovered in Porcupine as early as 1901, before Cobalt existed. As with Porcupine, so it has been with Kirkland Lake. In short, Cobalt may be considered the germinal source of modern precious metal mining in eastern Canada, if not the whole of Canada.

As was the case with the rich ores of Ballarat and Kalgurli in Australia, and Cripple Creek in Colorado, so the bonanza and easily marketed ores of Cobalt brought great wealth to those fortunate enough to become early interested. Money flowed to Toronto and other Ontario cities and towns, enriching men in every walk of life. Montreal felt the effect of the revival of Canadian mining, as also did New York and other American cities, especially Buffalo. London, not kindly disposed towards Canadian mining projects after its failures in Western Ontario and British Columbia, not unnaturally was slower to respond, but with the successful developments of the Mining Corporation at Cobalt, and still later of the Associated Gold Mines of Western Australia, at the Keeley Mine in South Lorrain, there was an answering echo, even in that great mining centre.

It is not only in Ontario that Cobalt money has been reinvested. Certain of the coal mines of Alberta owe their successful exploitation to Cobalt mines, while various mining and industrial enterprises throughout the length and breadth of the Dominion and even beyond its confines are financed by Cobalt money.

For twenty years Cobalt has been pouring forth a silver stream from its treasury of wealth. The zenith of production in ounces was reached in 1911; since that date there has been a steady, though fluctuating decline. The questions are often asked: "What is the future of Cobalt?" "Will the camp be rejuvenated by new discoveries?" Much light has been shed on this subject at various times by Miller's notable investigations, and more recently by the vigorous pronouncements of Knight.

The geological principles that govern the position of the ore deposits of Cobalt are well-known. The rich ore-shoots occur in close proximity to the contact of diabase sills, with Keewatin conglomerates and slates of the Cobalt series, or of greenstones of Keewatin age, — either within the diabase or within the intruded rocks, and in connection with both the upper and lower contacts of the sills. At first it was thought not improbable that the richness of the deposits had a close connection with nearness to the surface; but events have shown that this surmise requires marked modification. Mere depth below the surface — at any rate within the limitations of 2,000 feet — has in itself little if any bearing on enrichment. While there are obviously many other structural features to be considered by the seeker after new ore-shoots, the important factor to be borne in mind is relationship to the sill contacts.

In the section of the silver district immediately adjacent to Cobalt itself, the greater part of the easily-won ore, much of which either actually outcropped on the surface or occurred close to the grass-roots, would seem to have been mined; but until recently there has been little effort to prospect the deeply-buried contacts, excepting where they were followed downward along the dip of the sills, in the progress of practically continuous mining work from the surface. Within the last few years, however, a more courageous policy has been followed. The enterprising programme of La Rose in sinking a relatively deep

Nipissing's Low-Grade Mill.

shaft to prospect a hidden zone on its Violet property has met with success; within the last few months exploration at the adjoining Colonial mine has been similarly rewarded at greater depth. Even more interesting work is under way in the Beaver mine. Here, rich ores were mined both in Keewatin greenstone and in diabase along the upper contact by the original company, which had the temerity to sink a shaft 1,500 feet deep right through the sill, and commence exploration on the lower contact. Some rich ore was found, but comparatively little work was done, and it has remained for the Coniagas Company, which now holds the property, to take up the problem with renewed zest. Who knows what wealth may remain to be unearthed here and elsewhere along these deeper zones?

In the outlying sections of the silver districts courageous finance, backing geological hypotheses, is meeting with its reward. In South Lorrain, sixteen miles south-east of Cobalt, following a bright beginning in the successful operation of the Wetlauffer Mine, dark days fell upon the area, and it was not until success had attended the efforts of the London operators of the Keeley, whose sinister early history had served to retard the development of the locality, and later those of the Mining Corporation on adjoining properties to the north, that mining men directed serious attention to this isolated section. Today South Lorrain is going a long way to make up for the diminishing output from Cobalt itself.

Similarly, progress has been made in Gowganda, sixty miles north-west of Cobalt, where the Miller Lake-O'Brien Mine has been a wonderful producer for many years and where the adjoining Castle seems to be coming into its own.

The area in which veins of the Cobalt type are found, is large. Apart from those named, there are outliers from the central section at Rabbit Lake, thirty miles to the south; at Matabichouan, twenty-five miles to the south-east; at Casey, fifteen miles to the north-east; at Elk Lake, forty-five miles to the north-west; at Maple Mountain, thirty miles to the west, and elsewhere. In many, if not all, of these localities, surface indications would seem to be promising. Here would appear to be a wide field for detailed geological work, which should lead to the opening up of new and promising properties, or resurrecting hopeful prospects long since abandoned.

Gold Mining in Ontario

By BALMER NEILLY*

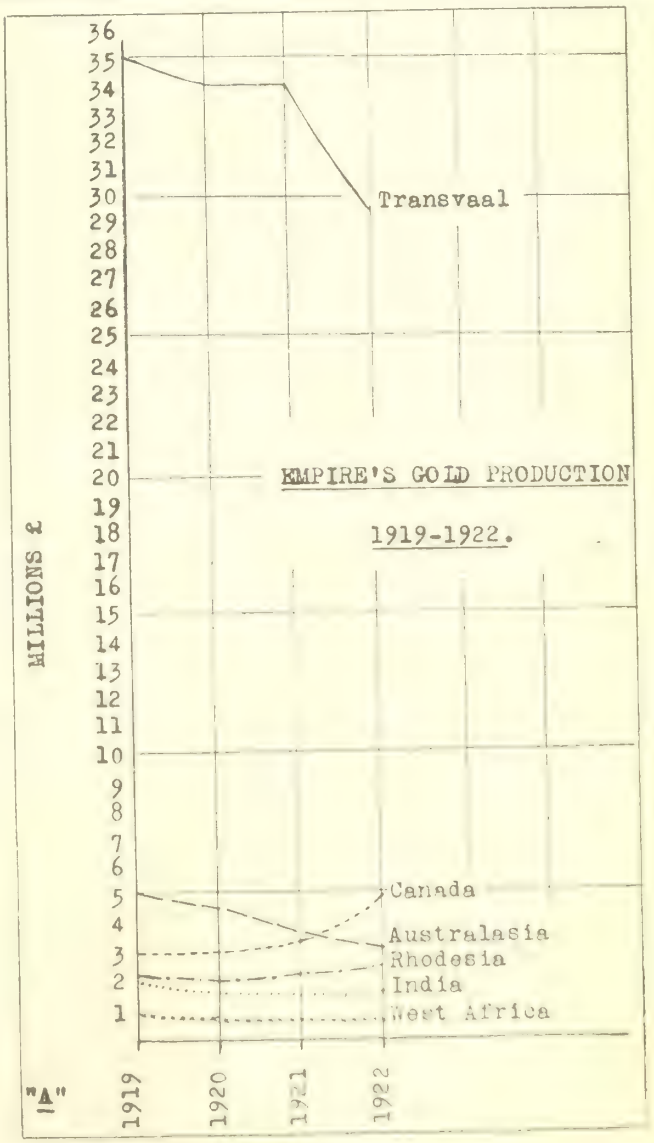
The reader may sometimes wonder why, lately, there is so much publicity given gold mining in Ontario, even to the exclusion at times of any mention of silver, nickel, copper and the production of other metals and non-metallic minerals. Some will say "it is the fashion;" but that explanation will not suffice. The commercial world is looking for gold. It matters not whether it is to be mined in South Africa or the Yukon, it is needed and must be obtained to provide greater elasticity in exchange. The record of every gold producing country is under constant scrutiny. With the world's gross production falling off, year by year, and one country after another posting decreased production, a country or province that increases its production by leaps and bounds stands out as a welcome relief. Ontario is that Province, and what is more natural than that the attention of mining investors the world over should be focused on the gold fields of Northern Ontario?

The relative position and the trend of production within the British Empire is indicated in graph "A," and when it is remembered that Ontario was responsible last year for approximately 80% of Canada's total gold production, the record of this province is apparent.

The American Gold and Silver Institute has estimated the world's gold production for 1922, and from their figures graph "B" has been constructed. This shows the percentage increase and decrease of each country's production in 1922, as compared with 1915.

Graph "C" indicates in a striking manner the rapid growth of the gold mining industry in Ontario during recent years.

The first discovery of gold in Ontario was made in Hastings County, in the eastern part of the Province, 57 years ago. Discoveries followed in the Lake Superior region in 1871 and still later in 1892 in the Rainy River district. The latter district was considered to have real merit, and for a time the future of gold mining in Ontario was considered full of promise. In 1899 our gold production was valued at nearly half a million dol



* Secretary, Ontario Mining Association

lars. But unfortunately the record could not be maintained. Production gradually dwindled, and by 1911 the value of our gold production had fallen to $42,637.

In 1909 the Porcupine camp was discovered. New finds were announced shortly after at Kirkland Lake and in numerous other districts, and while these two camps are at present the only producers, real progress is being made in outlying districts such as Larder Lake, West Shiningtree, Matachewan and in many other localities, probably just as important as these. Districts once abandoned are being re-opened in the belief that with modern and improved methods, costs can be reduced and operations made profitable. New production is coming from a point mid-

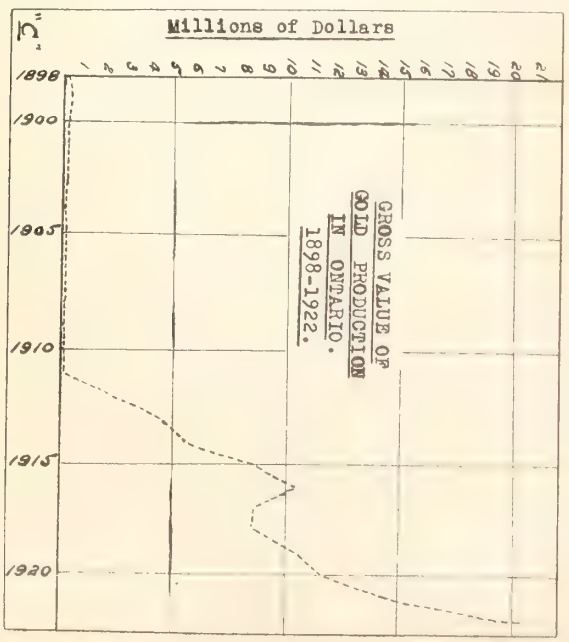
"B" WORLD'S GOLD PRODUCTION, Estimated by AMERICAN GOLD AND SILVER INSTITUTE.

way between Kirkland Lake and Larder Lake. At the latter point we are informed that mill construction may be expected in the near future. At Night Hawk Lake, east of the Porcupine camp proper, production may be expected early in 1924. Generally speaking, there is a feeling of optimistic expectancy throughout Northern Ontario, and it can certainly be said that to-day there is more prospecting being done and more serious mining development under way than at any previous time in the history of mining in Ontario.

To get a proper conception of the rapid growth in gold mining in Ontario, the reader is again referred to graph "C." While Porcupine was discovered in 1909, it should be noted that the camp at that time was made up of a few claims staked in a wilderness and 30 miles from the nearest railway. The preliminary work was faced under un-



usual difficulties; but enthusiastic faith and perseverance won out and the larger properties were approaching the production stage when the terrible fire of 1911 laid low the whole district, and the mining properties, so far as equipment was concerned, were back practically where they started.

In the meantime a branch of the T. & N. O. Railway had been constructed into Porcupine, and without hesitation work was once more commenced at the mines. Progress was rapid and most satisfactory. The mines here and at Kirkland Lake were just nicely out of the prospect stage and looking forward to steady production, when the war broke out. The best men exchanged pick and shovel for a gun. The companies in Porcupine and Kirkland Lake struggled along as best they could, but a labor shortage necessitated the curtailment of development work. High prices forced the treatment of ore higher in grade than the then mine average. Some mines were closed down.

Conditions toward the close of the war were very difficult, but to-day that is all changed. Men are available; increased hydro-electric power is being provided. The mines are responding favorably to development. Experience is establishing the cost of production and enabling the different mines to adjust their grades of ore to the required conditions and to estimate their positive reserves with some degree of accuracy.

In 1922 Ontario increased the value of its gold production over 1921 by approximately 41%. It stands to-day as the largest gold producing state or province on the North American continent, and everything points to a continued and satisfactory growth during the years to come.

Eighty-five per cent of the total area of Canada is largely dependent upon the mining industry for its colonization and development. Providence has dealt kindly with Ontario, but adjoining provinces share the ownership with us of the great pre-Cambrian area, and may in due time, in friendly rivalry, challenge our present leadership.

Too long have we estimated Canada's future upon the basis of its agricultural resources alone. Its mineral wealth and mining possibilities must be given the position their importance demands, and the day may not be far distant when mining may even challenge the leadership of agriculture, among the basic industries of this country.

To show that Canada's production of mineral wealth has been consistent and very satisfactory, the following table is appended—

How Value of Canada's Mineral Production has Increased.
Average Value of Annual Production over Five-Year Periods.

1887-1891, inc.	Average $14,[illegible]

THE KATANGA AND SOUTH AFRICA

The development of the mineral riches of the Katanga region of the Belgian Congo is of prime importance to the Union of South Africa, not only because it has afforded an outlet for the re-investment of profits from the gold and diamond mines, but because South African ports and railways will always serve that inland region.

Gold Milling in Northern Ontario and on the Rand

By G. J. MACKAY*

To mining engineers and metallurgists, especially those making their first visit to the mills of the Porcupine field, a short review of the history of milling practice in Northern Ontario and in the world's greatest gold field, the Rand, may be of interest.

Even those metallurgists engaged in the recovery of metals other than gold and silver find, from a practical as well as from an economic point of view, the developments and present practice in the recovery of gold not without interest. Many of them have had to do with the precious metals in their earlier years and most are more or less deeply interested in the wet treatment of ores, or its possibilities. The mechanical side of hydrometallurgy has, in most of its details, been developed in gold mills.

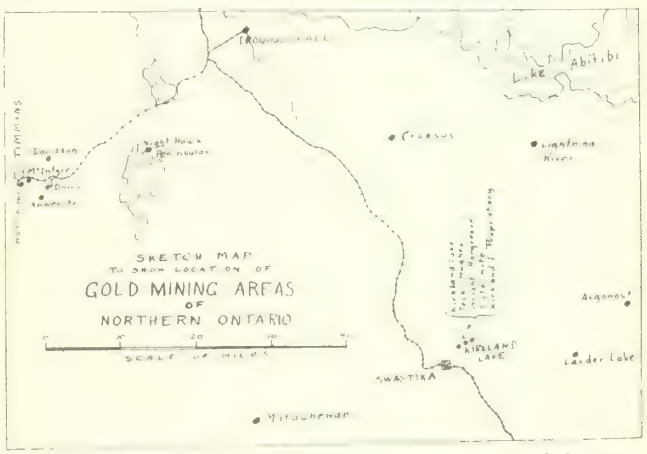
Ontario Has One-Eighth of Rand Production

Northern Ontario and the Rand do not make such an ill-mated pair for a metallurgical comparison. Although Ontario produces annually gold equal to only one-eighth of that produced yearly in the Transvaal, its mining field is young and is growing in importance, while the Rand is scarcely holding its own. The greatest gold field the world has ever seen had been a steady producer for twenty-five years when the first bullion bar was poured at the Dome mine in 1912. The great mines of Porcupine are scarcely into their stride; the Simmer and Jack and the Robinson, world famous for a generation, are nearing exhaustion and other scarcely less well known Rand mines are completely worked out. Yet, as old mines of the West and Central Rand are exhausted, new ones are brought into the producing list on the wide area of flat-lying reef of the Far East Rand. The younger field looks hopefully to the future; the older, after viewing with just pride a glorious past, turns with entire confidence to the prospect of a long and productive future. The man who speaks of Northern Ontario as the coming Rand is an optimist indeed: eight mines, large and small, are producing; all the larger and most of the smaller are increasing in stature; many promising properties are showing up well in development; new areas for the prospector are being discovered every year; but it will take many times these eight mines at their highest stage of development to make a second Rand.

Similarity and Contrasts

Of the great gold fields of the world, Northern Ontario and the Transvaal have ores, from the chemical point of view, amongst the easiest to treat. The gold dissolves readily in weak solutions with a low consumption of cyanide. Physically the ores resemble each other in some respects: each is low in sulphides, the Rand ore much lower than that of Ontario; in each, the greater part of the gold is very finely disseminated so that fine grinding is essential, though there is a considerable amount of really coarse gold in Porcupine ore and little in the Rand; in each 50 to 60 per cent. of the gold is free milling. But in the most important physical characteristic, they are entirely different: Ontario ore is comparatively soft and easily crushed, some of it being a very soft schist; Rand ore is one of the hardest and toughest met with anywhere and, also an important matter to the mill man, extremely abrasive because of the splintery nature of even very fine particles.

The differences in the methods of accounting in the two fields, especially the marked difference in the charges included in milling costs, makes a comparison of treatment costs difficult. Apparently in Ontario they are considerably higher than on the Rand. As to efficiency, conditions are so entirely unlike that a comparison is impossible. The difference in the crushing qualities of the



two ores has been mentioned. The types of labour are as far apart as they can well be: Rand mill men are all well trained by a long apprenticeship and Kaffirs do the unskilled work. The cost of supplies on the Rand is very high, as practically everything used is brought from Europe or America and five hundred miles inland by an expensive rail haul. Power is costly though generated from comparatively cheap coal. The one field has an extremely rigorous winter climate; the other has sunny summer days the year round with rarely a temperature of 90 deg. in summer and a little frost for a few nights only in winter.

Rand Practice a Steady Development

A comparison of the development of metallurgical practice on the Rand with that in Northern Ontario is not without interest. In the case of the Rand, the practice is distinctly a development and largely, until re

*Professor of Metallurgy, Queen's University, Kingston, Ont.

Panoramic View of McIntyre and Hollinger from the North

cently at least, a home product. Rand metallurgists, or most of them, are conservative. The Mines Trials Committee in 1911, tried out a home-made Dorr thickener—and condemned it; one of their leading metallurgists took much convincing in regard to the Butters filter. Some of them, however, would show themselves most progressive if they had a free hand. Most of the development there in the last twenty-five years has been along the lines of refinements in their own class of equipment and its use. In Northern Ontario, on the other hand, it has scarcely been a case of development. To begin with, ideas as to treatment were adopted from Rand and American practice. Some apparatus and some modes of procedure were found unsatisfactory and were replaced by others, as well or better known. The directing heads of the different properties were ready to install the most approved type of treatment plant and try it out on a working scale. In South Africa things moved in the self-contained English way; in Ontario, what was found perfectly satisfactory under similar conditions in any part of the world was considered good enough for at least a pilot mill. In the former case, development began from the days of the stamp mill with its amalgamating plates, before cyaniding was worked out; in the latter, nearly every present day crushing and cyaniding device was already on the market. and the flow sheet for a readily treated ore requiring fine grinding was pretty well agreed upon by American mill men.

In 1912, standard Rand practice included heavy California stamps with 1-4 to 3-8 in. screen openings; one tube mill (5 1-2 ft. by 22 ft.) to ten stamps with cone classifiers in circuit giving a product all passing a 60-mesh screen; amalgamation of the tube mill discharge; classification by cones to sand and through 200-mesh slime; sand leaching; Rand (intermittent) slime decantation treatment, and zinc boxes. New mills were departures from this in having screens to remove fine material from battery feed, 6 ft. by 16 ft. tube mills, Pachuca agitators, Butters filters, and zinc dust precipitation. No "standard" mills were replaced by this more modern equipment. Efficiency of crushing was compared on the basis of through 90-mesh (I. M. M. Standard) product. Some of the metallurgists on the Reef were beginning to doubt the efficiency of stamps and to look to rolls as an alternative; a ball mill had been tried and found to be a failure on the extremely abrasive ore. Some even then felt that they would like to try all-sliming as they believed that the additional extraction and low cost of slime treatment as compared with sand treatment would more than pay for the increased cost of crushing.

Ontario Mills Approaching a Standard Practice

At the time this stage in the development of Rand practice was reached, the Porcupine mills were erected. The Dome and the Hollinger copied the Rand as to means of crushing, but both decided that greater economy would come from all-sliming. The McIntyre was a step ahead in installing a ball mill instead of stamps. All three have retained all-sliming, the Dome departing from it in 1913 for the sake of greater tonnage at the least additional cost, only to return to it again in 1918 as the nature of the ore changed with deeper mining. The Dome alone used amalgamating plates in the tube mill circuit; the management is not sorry now that these were retained as their use results in a fairly uniform grade of cyanide heads from a most erratic day to day tenor of mine output. The Hollinger differs from most mills treating a fairly sulphide, readily cyanided gold ore in that they remove roughly a concentrate for special treatment. Their concentrating tables also serve much the same purpose as the Dome amalgamating plates by removing coarse gold. The men responsible for the operation of the Hollinger mill are convinced that the tables are worth while.

At the three mills, more confidence was placed in the newly developed means of handling slime than that shown on the Rand. The McIntyre installed Dorr equipment with continuous decantation to remove the gold solution; the Hollinger adopted Pachuca tanks and Moore filters to be followed shortly by an addition of Dorr equipment with continuous decantation; the Dome used Pachuca tanks and Merrill slime filter presses.

Later developments at Porcupine have been in the direction of the practice at the McIntyre. Rolls follow gyratory breakers to reduce the ore in preparation for initial grinding; ball mills were added instead of stamps when additions were made to the mills; the Hollinger, after exhaustive tests made in 1922, is to have its stamps replaced by rod mills. An interesting feature in Dome practice is the use of blankets below the amalgamating plates to catch liberated gold that does not amalgamate and high grade concentrate; the blankets retain more gold than do the plates. The three mills have, of course, Crowe installations for removing dissolved oxygen from the gold solutions on their way to precipitation.

The five Kirkland Lake mills are all of the same type, the type that Porcupine's experience of eight years or so seemed to indicate as the most economical for the district. In all, the ore is crushed to about 80 per cent through a 200-mesh screen by means of ball mills and tube mills charged with small steel balls, all the pulp is treated as slime, no amalgamation is practised, Dorr thickeners and agitators and Dorr counter-current decantation systems make up the uniform type of cyanide plant. One, the Teck-Hughes, uses filters, as does the Hollinger, to reduce loss of dissolved gold and cyanide in the residue from the continuous decantation plant. At both these mills the added cost is said to be justified.

McIntyre Mine and Mill, from the West, looking over Pearl Lake.

Modern Rand Mills

On the Rand, since 1912, development has been slow. There have been two very good reasons: few new mills have been erected, and the mills in use, built in a country where construction costs are high, have given good extraction at costs so low that to attempt to better them by scrapping expensive plants has seemed an extremely doubtful policy. One may summarize the lay-out of a typical Rand mill built in recent years as follows: Breaking in jaw crushers, washing, hand sorting of waste, breaking again, screening to remove ore already fine enough for the tube mills, crushing with Nissen stamps giving a 30-ton duty, tube milling using chunks of ore instead of pebbles (an old story there), amalgamation with plates in a separate building, cone classification to sand and slime, sand collecting and leaching in one set of tanks, thickening of slime pulp to remove excess mill water, air-lift agitation with solution, Butters filtration, Crowe de-aeration of solutions, and zinc dust precipitation.

The favourite successors to stamps in this country, ball mills or rod mills, seem as yet impossible on Rand ore. Rolls would seem out of court on such tough and extremely abrasive ore. Butters filters meet the situation in their slime plants: they are positive in action, giving a uniform tonnage and wash in warm and in cold weather; settling is much retarded when solutions are cold and any kind of slime settling plant is far from satisfactory there in winter.

New State Areas Mill

The latest Rand plant, the New State Areas mill, which began crushing in May last, is revolutionary as to Rand practice. Symons disc crushers reduce the ore to about one inch. This product goes to a tube mill-Dorr classifier circuit. The tube mills are 6 1-2 ft. by 20 ft., thirteen of them for a 1,700-ton mill. Amalgamation is not used. The ore is all-slime treated. The excess solution from the crushing plant is removed in square concrete settling tanks; Brown (Pachuca) tanks of double the usual horizontal cross-section are used; Butters filters are retained.

The radical departures are fine grinding without stamps and dispensing with amalgamation. The most interesting feature is the former. What is the cost of this additional fine grinding, and is the greater recovery from all-slime than from sand and slime sufficient to more than pay for it? Is the disc crusher the substitute for stamps that has been looked for so long?

It is probable that the more refractory nature of the ore the farther one goes east on the Reef has much to do with this radical change in treatment. At older mines, even twelve miles east of Johannesburg, it was early found that much finer grinding than that of common Rand practice was necessary. Also, for some years back amalgamation has been given secondary attention, no special effort or added cost being justified as "the cyanide would get the gold."

Tube Mill Practice and Blanket Strakes

A striking difference between Rand crushing practice and Porcupine is in the coarseness of the tube mill feed. It was found in the former case that feed as coarse as three-quarter inch was perfectly satisfactory: the larger pieces were broken, by the large "pebbles" used, soon after they entered the tube mill. The first pulverizing of Porcupine ores seems to be most efficiently done by ball mills; these, however, do not seem to be suited to the hard, abrasive Rand ore. At the New State Areas, the unusual number of tube mills for the tonnage and their great diameter mean that they will, with the large chunks of ore used as a crushing medium, do the work that the combined ball mill-tube mill units do in Ontario. However, the disc crushers and large ball mills, though ever so efficient on ore from the flat-lying reef of the deep-level mines of the Far East Rand, may be quite unsuited to other Rand ores. The greater pressure of hanging wall on this flat reef has resulted in considerable fracturing of the ore, making it more easily crushed.

Lake Shore Mill, Kirkland, (now being enlarged)

A recent innovation in many Rand mills is the replacing of amalgamating plates by corduroy blanket strakes, not simply adding them below the plates as at the Dome. These catch most of the liberated gold and the "black sand" concentrate. The blankets are periodically replaced and washed. The product is graded on a Wilfley table and the greater part is ground in a small ball mill with mercury and the resulting amalgam retorted. This reduces the loss of mercury, lowers labour costs, removes the danger of amalgam theft, and makes possible crushing in cyanide solution with its advantages of shorter treatment and less mechanical loss of cyanide and gold with the tailing. As to mercury poisoning, at its worst it affected only the men who did the retorting and melting and still have it to do.

Evidently most Rand mill men continue to believe in lowering the gold in their cyanide heads as much as possible without too great expense.

Rand Metallurgists Conservative but Alert

An American gold metallurgist looks upon his Rand confreres as extremely conservative. However, he must consider the conditions they have to face: Directors at a distance guide the destinies of many of the mining companies, the plants are large, construction costs are very high, the ores are unusually difficult to grind, and the mill workers, especially battery men, are perfectly trained by a long apprenticeship and years of service so that the operating of present equipment is nearly perfect. To desert well-tried friends for new, however attractive, makes anyone pause. Every Rand metallurgist must be more than interested in the outcome of the departure at the New State Areas; without a doubt some of them have had hopes of some day being free to make just such a grand experiment.

It is interesting to note here that fifteen years ago crushing in cyanide solution had been practised for some time in the mills of one Rand group, and that a type of continuous decantation was tried in connection with it. Also it has been claimed that an "air lift vat" was in use on the Rand before Brown's Pachuca agitator was known there.

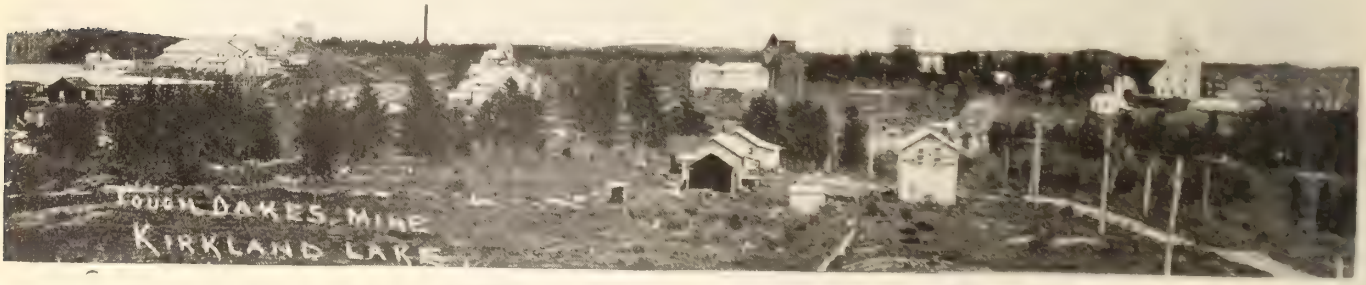
Nowhere did the Crowe process receive a warmer welcome than on the Rand. The very weak cyanide solutions possible and therefore most desirable in treating their slime made zinc dust precipitation unsatisfactory; even with zinc boxes much trouble was encountered with the weak solution, an excessive amount of "white precipitate" forming; the Crowe process removed these difficulties and reduced the consumption of cyanide and zinc.

A visitor to a Rand mill, except a very old mill, may well admire it and its operation. The mill is designed for a certain flow sheet, built along the lines laid down, operated for many years more like a factory than a mining plant, maintained in the best of repair and kept neat and clean by "cheap Kaffir labour" and the operators are skilled from long practice in that or a similar plant. The stamp mill, especially, and its operation are models. The long life ahead of the mine makes for substantial plant construction and the conservative policy of the directors does not favour changes during or after erection. To crowd tanks and other equipment under as small a roof as possible is unnecessary in such a climate; much of the plant is in the open, even the tube mills at some plants.

A Rand Plant in Panorama

Many details are rather striking to an American visitor. Lack of space makes tailing disposal an expensive operation in many mills: sand dumps are like small mountains and can be seen stretching in a white string toward the horizon; slime dams are built up in their own growing slime walls to a height, at some older mills, of nearly 100 feet. Mechanical equipment is as simple as it is possible to make it; the average English engineer looks upon the American as a man of complex mental processes who delights in concrete evidences of them. The mills are on level ground, much pumping is essential, and head for flow is the least possible for the sake of power economy. Bucket elevators and plunger pumps have gone the way of the conspicuous old tailings wheel and pohle air lift; centrifugal pumps are used for every possible purpose. Pumps, when at all possible, even at the expense of much piping, are grouped in one building; all receive their supply from above their own level; belt drives are favoured to avoid motor trouble from spills. Cone classifiers have been, until recently, the only kind used; they do good work but require ingenious devices for regulating the under-flow. Except in the latest mills, one well located point will give a view of battery, tube mills, and plates; a second, a view of the open air cyanide plant, except the extractor boxes. The flow sheet can be seen spread out almost as on a printed page; there is room for a straight-away lay-out that is not possible in the cold winter climate of our northern or mountain gold mining districts.

Porcupine, and especially Kirkland Lake, are comparatively new fields untrammeled by tradition or fixed mill practice; the Rand is an ancient as gold fields go and is set in its ways. The former began with largely "modern" practice and is rapidly perfecting it; the latter is coming slowly to similar systems of gold ore treatment, but with admirable caution, giving due consideration to undoubted advantages in such treatment of their more refractory ores, but never losing sight of the low costs and high extraction of their own well-established practice.



Tough-Oakes Mine, Kirkland Lake, and Adjacent Properties

Porcupine Gold Deposits*

With Special Reference to Producing Mines

By A. G. BURROWS**

The Porcupine gold area is situated in the northeastern part of Ontario, being part of the district of Cochrane. The south boundary of the township of Tisdale, in which are situated the large producing mines, in in latitude 48° .27′-54″. The principal town is Timmins, which is 485 miles distant by rail from Toronto.

The area first attracted general attention when gold was discovered on a number of claims in 1909. Several of the earliest discoveries were on properties that developed into large mines. The precious metal has been found on a great number of claims in the area, but only few of the discoveries have so far been developed into profitable mines. The problems of structural relations are gradually being solved in the camp, and it is reasonable to believe that additional mines will be added to the list. Until the advent of Porcupine the mining of gold ore in Ontario had not been a profitable venture.

Production

Since the discovery of gold in Porcupine, the area, up to the end of 1922, has produced $96,341,098, or about 89 per cent. of the total gold won in Ontario. The greater part of this gold has been extracted from ores from the Hollinger, Dome, and McIntyre mines, while smaller mines, like the Porcupine Crown, Vipond-North Thompson, Newray, and Dome Lake have contributed respectable amounts to the total. Some gold was also obtained from the Davidson, Clifton, Porcupine Pet, and Three Nations.

During 1922, Porcupine produced $18,592,087 in gold (including some silver), which represents about 73 per cent. of the total production of the Dominion of Canada during that year.

Geology

The principal rock formations of the Porcupine area belong to the older part of the pre-Cambrian. The oldest rocks are Keewatin age, predominantly lavas, which are now so altered that in many parts it is impossible to name them specifically. They are much changed mineralogically and structurally from their original condition. .The lava flows in the main part of the area were likely of basic to intermediate composition, basalts, andesites, and dacites, now much altered to schist. The flows, of which there is an orderly succession, are thrown into synclinal and anticlinal folds. Rhyolite is a prominent rock in parts of Whitney and Deloro, and the southeast part of Tisdale. Field work in 1922 has shown a strong synclinal structure in the central part of the area; this fold rises towards the west. On the north and south limbs of the fold a succession of lava flows has been recognized. The basin between the limbs is occupied by folded sediments of Temiskaming age. The structure is really a synclinorium with minor anticlines and synclines occurring near the southerly limb. The structure is of great importance since the Dome mine is located along its southerly margin where a deep deposit of conglomerate, greywacké, and slate lies in a synclinal trough of Keewatin rocks.

Field evidence was secured to prove that there had

* Paper read before the Royal Society of Canada, May 1923.
** Department of Mines, Toronto.

Gold Quartz Veins. Dome Mine

been some folding and erosion of the Keewatin prior to the deposition of the Timiskaming sediments. This evidence was based on the recognition of the succession of lava flows with their clear-cut contacts eroded, and sediments deposited across the flow contacts.

The structure of the Keewatin rocks in the vicinity of the Hollinger and McIntyre mines is not yet clearly understood. The presence of infolded Timiskaming sediments three-quarters of a mile west of the Hollinger mine suggests a north-south anticlinal structure

"The Dome" of Gold Quartz

in the area east of the mine from which the Timiskaming sediments have been removed by erosion. The structure of the Keewatin is of importance since some evidence has been obtained by H. S. Robinson, geologist of the McIntyre mine, to indicate gold-bearing veins occurring along lava-flow contacts.

A third series of important rocks is the Algoman. This includes quartz-porphyry, feldspar-porphyry and granite which occur as stocks and dikes intruding the Keewatin and Timiskaming. There is evidence to show that the intrusions of the porphyry were responsible for the gold deposits of Porcupine. It is very significant that all the great mines are located where the older rocks were intruded by the quartz-porphyry. Underground operations have proven the porphyry stocks to pitch in an eastern direction at high angles, 50° or so, at the Hollinger mine, indicating that the porphyry magma rose from some source lying to the east of the present outcrops. The porphyry is a light grey rock in which phenocrysts of quartz are generally recognized, while acid plagioclase is the principal feldspar. Ferromagnesian constituents are usually lacking. The rock is much altered and rendered schistose. Secondary hydrated mica is abundantly present in the altered rock, much of which could be called a sericite schist. The end margins of the elliptically shaped outcrops of porphyry are often very ragged, showing tongues projecting into the volcanic schist. The structure of the masses of porphyry in the Pearl lake area has been worked out by W. H. Wylie and H. S. Robinson, geologists at the Hollinger and McIntyre mines respectively.

Masses of serpentine and dikes of olivine diabase and quartz diabase occur in parts of the area.

Ore Deposits

The gold deposits occur in the Keewatin, Timiskaming and Algoman. Of these the most important at the present time are those in the Keewatin lavas which represent practically all the producing areas of the Hollinger and McIntyre.

The conglomerate and greywacké carry about 90 per cent. of the ore at the Dome mine, with minor quantities in the Keewatin and porphyry.

The mineralization of the deposits is believed to have followed the intrusion of the quartz-porphyry.

The longer axes of the porphyry masses roughly parellel the schistose structure of the volcanic flows and it seems probable that the Keewatin and Timiskaming were partly folded and metamorphosed before the intrusion of the porphyry. The porphyry itself has also been subject to great pressure, being schistose in many of the outcrops.

The intrusion of the porphyry at different horizons produced stresses, which were relieved by the forming of shear zones approximating the direction of schistosity. These shear zones were the loci of the mineral-bearing lodes and replacement deposits.

The deposits are lenticular in shape, such forms being particularly characteristic of those enclosed in schist. In one deposit there may be a series of lenses arranged "en eschelon", constituting a lode. Often, in driving on a lode, it is found that successive lenses lie to the left hand.

The ore deposits of the Pearl lake section can be referred to as a lode system in which there is a series of lodes, or veins, striking from about N.20°.E. at the southwest end of the Hollinger to nearly N.80°E. at the McIntyre, the system having a roughly crescent shaped outline. Branching veins occur with main veins, affording a very complicated series to develop

The Dome Mine in 1910

and stope. Some individual veins have been drifted on for a considerable length. No. 12 vein on the Hollinger was 1,500 feet long on the 200-ft. level, and No. 1. vein at the same mine has a length of about 1,000 feet. No. 5 vein at the McIntyre was 1,500 feet in length. The lodes for this area average about 8 feet in width, although, owing to their lenticular form, stopes are sometimes required as wide as 40 feet in places. Most of the lodes have no definite walls, the limits of a stope being determined by the assay value.

Character of Lodes

The Porcupine deposits, with special reference to the Hollinger-McIntyre area, are, technically speaking, lodes or composite veins, although referred to generally as veins. They consist of mineralized schist with stringers of quartz, or large masses of quartz enclosing strips of altered volcanic rock. The quartz in the deposits is extremely irregular, so that each successive round in drifting on the veins displays a greatly varying distribution of the quartz and schist. The quartz may run with the schist or cut obliquely across it, while streamer-like veinlets may run transversely into the walls. Abrupt bends or folds in a vein usually show a high gold content and much visible gold may be present. The mineralized schist part of a lode usually predominates over the quartz, but some veins are largely quartz, like Nos. 12 and 97 at the Hollinger. The deposit mined at the Porcupine Crown Mine was a much contorted, banded quartz vein.

Relation of Gold Deposits to Porphyry

An examination of the geological map of the Pearl lake section of the area will show numerous masses of porphyry, the largest and most important of which is that which partly underlies Pearl lake and stretches southwesterly on to the Hollinger mine. This stock is about 6,000 feet long and 1,400 feet wide. Most of the ore-bodies at the Hollinger mine are clustered round this stock, the surface plan showing many veins extending beyond its southwesterly outcrop, and lying along or near its flank and that of other smaller masses of porphyry. The westerly end of the large stock, as seen distinctly on the Hollinger property on the surface, is found in its pitch to the east, on the McIntyre on the 1,350-foot level about 300 feet east of the west boundary of the property, opening up an area of volcanic schist favourable to the deposition of gold behind the retreating porphyry. Here a number of gold-bearing veins have been found similar in structure to certain veins which were first encountered in the Hollinger mine at higher levels, or on the surface beyond the porphyry.

Mining operations have shown some gold deposits to occur along fracture zones which have extended from one porphyry stock to another.

While the porphyry is a necessary rock in the formation of the gold deposits, mining operations in the Pearl lake area have proved it to be unfavourable as a container of ore deposits. Profitable veins in the volcanic schist have been found to lose their value or become too low-grade to mine where they enter the porphyry. Veins, which in part of their course lie along the contact of porphyry and volcanic schist, are often favourable for ore. There are also deposits in which a thin strip of mineralized basalt or andesite enclosed within the porphyry walls constitutes a workable vein.

Minerals of the Deposits

The deposits were formed at a period subsequent to the intrusion of the porphyry, the magmatic solutions probably being supplied by a deeper part of the parent magma. The earliest of the minerals is quartz, which in character and structure resembles quartz of pegmatitic origin, showing coarse, granular texture and gas and liquid inclusions. Feldspar frequently accompanies the quartz, being found largely along the contact of quartz and schist. As suggested by Gratton in his description of the veins of the Southern Appalachians, it is possible that the vein-forming solutions representing the final products of emanations of a granite magma were injected under heavy pressure into the surrounding rocks along lines of weakness, and so, like pegmatite dikes, made a space for themselves by opening their own fissures. Such a mode of formation would explain the very irregular forms assumed by the quartz masses in the gold deposits. It is found that the primary quartz is very much shattered and the crushed areas cemented by later quartz and "carbonate." It is usually in these areas that most of the visible gold and sulphides occur.

The most abundant and earliest of the sulphides is iron pyrites, which occurs abundantly in the schist surrounding the quartz masses and to a lesser extent in the quartz. The pyrites is well crystallized in cubic and pyritohedral forms with occasional octahedral faces, particularly in the schist where, with other minerals, it replaces the latter. The crystals of pyrites are generally accompanied by blotches of quartz, sericite and "carbonate" and, occasionally, chlorite. Galena, zinc blende and copper pyrites occur in minor quantity, usually near the contact of the quartz and schist in the quartz or carbonate. In this association of minerals there is frequently visible gold.

Arsenical pyrites and pyrrhotite have been recognized in Hollinger ore, and the rare mineral scheelite, calcium tungstate, is occasionally found in the quartz as an early constituent. Tourmaline is present in many of the deposits, and its bearing on temperature of formation will be referred to later.

The schist ores of the Hollinger-McIntyre system are usually light grey to dark grey in colour, due t abundant carbonate and other secondary minerals. Microscopically they usually show quartz, carbonate, sericite, leucoxene, pyrites, and sometimes chlorite and feldspar in varying proportions. Analyses of mineralized schist from the Hollinger veins have shown an increase of potash and a decrease of soda

The Dome Mine, Today

over that of the unmineralized volcanic rocks of the area. It is suggested that the hot ascending alkaline solutions have replaced the silicates of the rock with sericite, which occurs profusely in a stream-like arrangement of minute blade-like crystals.

Temperature of Formation of the Deposits

Lindgren in his work, Mineral Deposits, groups the Porcupine veins with those deposits that were formed at high temperatures. He states that certain characteristics of the veins resemble those of California which he classifies with deposits formed at intermediate temperatures. High-temperature minerals are not abundant in the Hollinger-McIntyre ores, but tourmaline and pyrrhotite are occasionally seen.

Tourmaline is abundant in some of the Dome ore, particularly from ore- shoot No. 731 and others near the contact with the quartz-porphyry. In ore-shoot No. 731 great masses of conglomerate, greywacké and slate, where lying between two masses of porphyry, have been largely replaced by tourmaline. This ore, which is brown in colour, due to tourmaline, is heavily pyritized, high-grade, and the hardest ore in the camp. Thin sections of porphyry from the vicinity have shown tourmaline as a constituent of the rock, and the tourmaline of the ore has evidently been derived from the porphyry magma.

Pyrrhotite is quite a common mineral in the Dome deposits, usually occurring in fairly large masses with the quartz.

Tourmaline is a characteristic mineral of several gold-bearing quartz veins in the north parts of Whitney and Tisdale township, and a notable constituent of quartz veins in the porphyry on the ridge on which are located the Paymaster and Clifton properties.

Axinite, a boron-bearing silicate, occurs with quartz in veins on the Moneta property.

It is probable that tourmaline in some occurrences is an early constituent along with the quartz, as in vein 44 of the Hollinger. Here the mineral is in glassy quartz, while milky-white quartz carrying pyrite and gold is of later origin.

Dome Mine

The Dome mine differs in geology and structure from the mines near Pearl lake, and requires to be discussed separately. An additional series of rocks, the Timiskaming, is found here. The structure consists of synclinal and anticlinal folds in which a crest line of Keewatin volcanics controls the location of the ore-bodies. The Keewatin crest line outcrops to the west of the large open pit and with a strike N. 60°E pitches at 40° under the conglomerate, greywacké and slate of the Timiskaming series. On the south side of the Keewatin crest there is a deep fold of Timiskaming sediments, the contact dipping almost vertically. On the north side of the Keewatin, the sediments dip gently to the north It is mostly along the crest line, partly in Keewatin, and partly in the sediments, and in the deep sediments to the south of the Keewatin, that the large ore-bodies of the Dome are found. The ore zone on its south side is flanked by intrusions of quartz-porphyry which, on some levels, form a hanging-wall for certain ore deposits. The ore-bodies are large and irregular in outline and are wide in proportion to their stope length. They vary from 15 to 150 feet in width, some being over 500 feet in drift length. Certain shoots have been found to extend vertically for 600 feet. Two stopes were opened up in quartz-porphyry and a few are in the Keewatin , including what is called the telluride stope on the eighth level. About 90 per cent. of the ore has been obtained from conglomerate and greywacké of the Timiskaming series. The ore-shoots are nearly vertical, except when occurring along the crest line of the Keewatin, or when influenced by overlying slates which dip easterly over some of the ore deposits. The slates were too fine-grained for the circulation of ascending solutions and acted as a dam, so that rich ore is often found directly below them. The ore is mineralized schist derived from sediments, Keewatin volcanics, or Algoman porphyry, together with irregular masses or veinlets of quartz. The quartz constitutes probably from 10 to 15 per cent of the ore.

The ore contains a high percentage of sulphide minerals, and usually a high pyrite content indicates an increase in value. There is a great variety of metallic minerals, including pyrite, pyrrhotite, copper pyrites, galena, zinc blende, arsenopyrite, altaite, and a silver-gold telluride. Tourmaline is abundant in certain stopes near the porphyry, while scheelite is occasionally found. The ore contains a good proportion of carbonates. The ore structure has been carefully worked

Lode Structure, McIntyre Mine

out by D. G. H. Wright, geologist of the mine, to whom the writer is indebted for much information.

The main shaft has been sunk to 1,600 feet, while on the 12th level (1,450 feet) development of ore is now in progress.

In 1922, there were milled 365,400 tons and $4,178,[illegible] in gold was produced The recovery was $11.34 per ton with an extraction of 97.8 per cent. The average of the past year apparently shows that the ratio of gold to silver in the ore is 6.7778 to 1. The total fineness of bullion is 983.9 gold and silver.

Development of Mines Near Pearl Lake

The McIntyre mine has the deepest working of a gold mine in the Province. No. 5 shaft is sunk to the 2,450-ft. level, while there are extensive workings on the 1,875-ft. level, particularly on Nos. 7 and 9 veins. No. 6 vein, showing visible gold, was encountered in No. 5 shaft at a depth of 2,150 feet.

During 1922, the McIntyre mine produced $2,137,372 from 217,208 tons of ore, or a recovery of $9.84 per ton.

Mining operations have been carried to the 1,250-ft. level at the Hollinger mine, where the lode system is now being developed. One shaft is down 1,530 feet. In the statement of ore reserves in the annual report of the company for 1922, it is said that 55 veins show values from $32.80 to $6.10 per ton. During the same year nearly 1,500,000 tons were milled with an average value of $8.53, from which $12,274,114 was recovered.

Each of the three large mines has a geological staff whose chief duty is to aid in development by mapping the structure from evidence obtained in drifts, cross-cuts, and other workings, and from examination of diamond drill cores from many parts of the mine. Diamond-drilling is carried on constantly at each property, and has been very effective in locating and following up very irregular ore-shoots. Many short lenses of ore have been discovered by this means that otherwise might have been missed.

MINING IN QUEBEC

By JOHN A. DRESSER*

Viewed broadly, the mining industry in the Province of Quebec, may be said to be long in history, short in production and large in promise. Within the lifetime of the original European inhabitants of Montreal, founded in 1642, iron ores became known and were utilized in the St. Lawrence valley, and within 100 years silver-lead ore on the shore of Lake Temiskaming was indicated by a map of the period published in France. About 1733 the use of the iron ores was so important that a mining company was formed in Quebec to supply the needs of the colony from the bog iron ores of Three Rivers. This operation was carried on more or less continuously until some fifteen or twenty years ago, when the last small blast-furnace of early use was dismantled. There is, of course, no complete record of the production of this small but persistent field, which is now known only as a producer of ochre. Its product was given a place in the literature of the province by the late Dr. W. H. Drummond, poet of Quebec's rural life, in describing the Winter comforts of the "habitants", who reflects on —

"De old stove from Tree River
My wife's fadder geev her
De day we get mariés,
Dat's long time ago—"

Retrospective

In 1824 alluvial gold was found in the pre-Glacial gravels of the Chaudière valley and mining operations were carried on intermittently during the latter half of the last century. A production of $3,000,000. is estimated to have been made from this district, the major portion being recovered from a small area and in about ten years of this time. The engineering difficulties due to deep overburden and water were a serious handicap to the operations of that time. It seems worthy of note that these gravels have not been thoroughly investigated in the light of modern practice.

Copper, known in the province since 1841 at least, was worked vigorously in southern Quebec during the period of the Civil War in the United States. Following the post-war depression several properties were re-opened. One of these, re-opened in 1875 by the late G. H. Nichols, formed the basis of an important sulphuric acid industry. Another, the Eustis mine, near Sherbrooke, has been in practically continuous operation from 1880 to the present time. It is the deepest metal mine in Canada, being well over 4,000 feet. Records of the total production of copper in Quebec are not available. In 1918, the high mark of the Great War period, the output was 5,869,000 lbs. The ores are sulphides, principally chalcopyrite, and occur mainly in sheared porphyry and related volcanic rocks. Pyrite has been an important by-product of these operations. It was in the early development of these ores that the late James Douglas began his brilliant career in copper metallurgy.

Chromite, previously known for some years, was first exploited in Quebec in 1861, the ore being exported to Scotland. The venture proved unprofitable. Since 1894, however, chromite has been mined in irregular quantities but almost continuously under the stimulus of better railway facilities. The total production has been approximately 200,000 tons.

Phosphate was mined in the western part of the province in the valley of the Ottawa River from the year 1877, until displaced in the market by the more readily available deposits of the southern Appalachian States. Exports from the province of Quebec for the thirty years following 1877 amounted to 270,000 tons.

Graphite has been mined intermittently in the Ottawa valley in Quebec since 1846. The total production is not known; that from 1898 to 1918 was valued at $386,540.

Mica is mined in various parts of the pre-Cambrian area of Quebec, principally in the vicinity of the Gatineau and Lièvre rivers, tributaries of the Ottawa. The chief product is phlogopite or amber mica. In 1913 the production amounted to 626 tons valued at $125,488; last year to 444½ tons, valued at $90,518.

Asbestos. —When one speaks of mining in Quebec he is supposed to refer to asbestos, unless he specifies otherwise. Although discovered in 1847, it was not commercially developed until thirty years later, when the construction of the Quebec Central Railway to the field was accomplished. Since the latter date it has grown to dominating importance in the mining industry of the province, and for the past thirty years the major supply of the world has come from Quebec. Its excellent quality, large reserves and favorable transportation facilities have resulted in a large and stable development. The maximum production, attained in 1920, amounted to nearly 200,000 tons having a value in round figures of $15,000,000. Asbestos is the subject of a separate article in the present issue of the *Journal,* from the authoritative pen of Mr. Norman R. Fisher, and need not, therefore, be further discussed here.

Magnesite, molybdenite, zinc and lead are minerals that attained a production of commercial importance in Quebec during the war and more recently. Feldspar has been making recently a sensible output.

* Consulting Mining Engineer, Montreal.
President, Canadian Institute of Mining of Metallurgy.

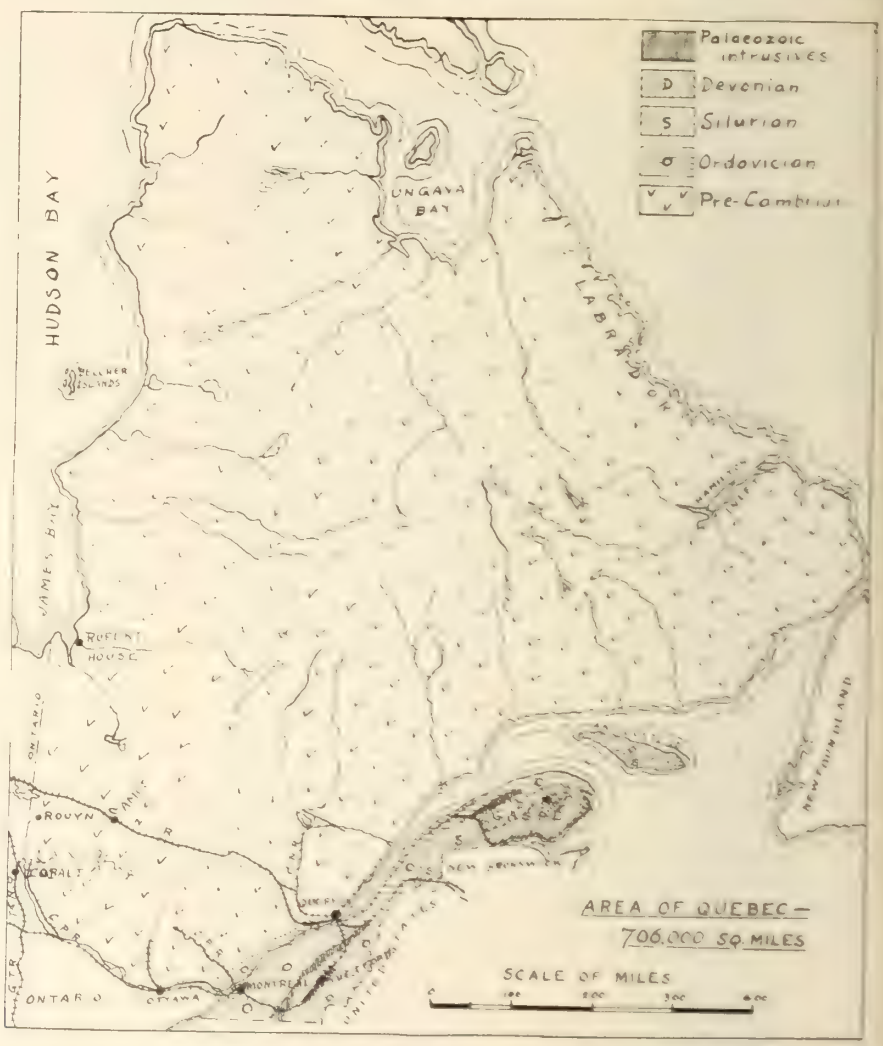
Prospective

Notwithstanding its long and rather commonplace history, the mining industry of Quebec has decidedly promising prospects for early future development.

On the south side of the St. Lawrence river there is a large tract in the Gaspé peninsula which gives promise of repeating the values already known, and in part obtained, from the same formations in the more southerly part of the province. A large area in this region is now being developed for zinc, lead and copper, with strong hopes of success.

Petroleum occurs in the Devonian measures of Gaspé and may yet be found in useful quantities in the less disturbed Paleozoic strata of this region, or in the Island of Anticosti. Alluvial gold in the Chaudière and Ditton valley has been already referred to and is not without prospective value.

Only a small corner of Quebec Province is served by railways. The Ungava Peninsula has been traversed only at wide intervals, yet large areas of the mineral-bearing series of rocks have been located roughly. Little prospecting has been done, even on the coasts of the peninsula. The interior of Gaspé is almost unknown to the prospector



North of the St. Lawrence River, the Province of Quebec consists mainly of a portion of the Laurentian Plateau, or "Canadian Shield". The major portion of this region is, of course, little known as to its mineral products, save that it is underlain by rocks of pre-Cambrian age which in neighboring Provinces and States, and as far as is known in Quebec also, contain a wide range of useful minerals. The total area of pre-Cambrian formation in Quebec is about 600,000 square miles. Speaking of all this region, Mr. T. C. Denis, Superintendent of Mines for Quebec, has recently observed that its productiveness is in general proportion to our knowledge of its resources, that is to say, to its settlement. Aside from such resources as have been mentioned as occurring within this settled part of the Province, it is significant and encouraging to recall the production that has been made from the pre-Cambrian rocks of the older settled regions of New York, Michigan, Wisconsin, Minnesota and Ontario. Of these the most generally applicable comparison is to be made with the Province of Ontario, whose better exploration and development have shown immense resources in territory of similar character and adjacent to the Province of Quebec.

Besides the extraordinary deposits of Sudbury and Cobalt, the annual production of gold ore from Ontario is rapidly reaching preponderant proportions. Yet some sixteen or seventeen years ago a geologist setting out on a prospecting expedition to the North was directed by his principals to spend no time in the search for gold, since an eminent financier, still prominent in the country, had fully assured himself that there was no gold of importance in Ontario or Quebec. Since that date a small corner of Northeastern Ontario has produced nearly $100,000,000 in gold, and has repaid more than a quarter of that amount in dividends. In view of the splendid success of that Province in recent years, the hope that the closely related province of Quebec may develop a large mining industry seems well founded.

It would be difficult to over-estimate the value to this province of the experience gained by the province of Ontario in the development of its mining industry. The successful utilization of its mineral resources seems to be due in large measure to two features in the policy of the Province.

The building of the Temiskaming and Northern On-

tario Railway, twenty years ago, into the then little known North, has added to the province an immense mineral production as well as a large and profitable agricultural region.

Concurrently with this exploratory venture the Province of Ontario built up a Bureau, now a Department, of Mines, of the highest efficiency in guiding the utilization and adding to the discovery of mineral resources. The work of this Department has been expanded as the need, or rather as the opportunity, for service arose. The contributions made by it to the mining industry are of the first order, and its reports are a necessary part of the equipment of all workers in similar fields throughout the world. The administration of mining lands so as to facilitate their development and give due returns to the Province has been done with equal distinction.

There is now opportunity for Quebec to supplement, as well as to profit by, the results of this commendable policy. In transportation facilities, water power, timber and other supplies for mining equipment Quebec is favorably circumstanced. The Canadian National Railway between Cochrane and Quebec opens a section of some 500 miles along its course, and also affords access to many navigable rivers that extend far into the interior. The Canadian Pacific Railway is building an extension of its line on the East side of Lake Temiskaming to the Quinze River, on which are a series of notable water falls, and soon will be in a position to serve the new prospecting district of the Province.

The water powers of the Province are on a large scale and powers either developed or undeveloped occur within transmissible distances in any part of the province. Timber is everywhere available for mining purposes, and the rapid settlement of agricultural lands in newer portions of the province assures moderate living costs, and in many places local supplies of labor.

The Department of Mines of the Province of Quebec is an admirably efficient office in all but its size, which is totally inadequate. Previous to 1909 its work was only on a nominal scale. Following a well directed enlargement at that time, the mining laws were brought into harmony with those of other mining provinces, and reports of a superior character have ever since been produced. But although the mineral production of that time was less than $6,000,000 and has now risen to $18,000,000 or $20,000,000, there has been no enlargement of this Bureau to correspond to the increased needs, nor in fact any fundamental enlargement at all. One deputy recording office has been opened recently at Ville Marie, in the West end of the Province, but the Department is not equipped either for adequate inspection of mining operations, or for exploration of new areas. In fact it must under these circumstances merely record mining operations, or for exploration of new areas. The efficiency of its work, however, when these limiting circumstances are considered, is really remarkable. But the Department must be substantially enlarged, more especially in its technical staff, before the Province of Quebec can avail itself of the enlarged opportunity now before it.

Gold in Northwestern Quebec

By A. O. DUFRESNE*

From lake Temiscamingue extending north to James Bay is a vast stretch of flat country that has been described as the "Abitibi Clay Belt". It is a plateau of post-glacial clays, extending approximately as far as Bell river to the east, and on the south to the divide between the Hudson Bay slope and the St-Lawrence river basin. This plateau, which extends on both sides of the Ontario-Quebec boundary, is mostly underlain by pre-Cambrian rocks consisting of Keewatin volcanics, Temiscamingue and Cobalt sediments, and igneous rocks of intermediate and subsequent epochs. The rocks of this system are known to contain elsewhere rich deposits of the precious metals.

The results of geological explorations in Northwestern Quebec have brought to light the extension, into that section of the Province, of belts of rock favourable in Ontario to the occurrence of gold.

It is only within the last twenty years, after the discovery of the spectacular silver deposits of Cobalt that mining men have turned to the Hudson Bay slope as a field for mineral exploration. Since then, every summer, hundreds of prospectors have travelled by canoe the numerous lakes and rivers of the northern watershed. Railroad facilities offered by the T. & N O. Ry. and later by the National Transcontinental Ry., and the help of the Provincial geologists in promptly mapping and reporting on the areas of new discoveries, have attracted to Ontario a large number of able prospectors. Their searches have borne fruit; already a score of gold producers have been developed. Previous to 1912 the gold production of Ontario was below the $100,000 mark, while last year the mines of Porcupine and Kirkland Lake yielded $20,000,000 of the precious metal.

The discovery of rich ore-bodies in these two camps and of important occurrences at a number of other places have prompted mining men to examine similar formations extending east of the interprovincial boundary into Northwestern Quebec. The accumulation of geological data in the gold areas of Ontario and the exploratory mapping of geological formations in the adjoining sections of Quebec have brought forth evidences of the occurrence in Northwestern Quebec of a gold-bearing zone probably of economic importance,

Workings on the Powell Vein, Rouyn Township

* Assistant Superintendent of Mines, Quebec.

following the trend of the belt of Temiscamingue sediments on which are located the Matachewan, the Kirkland Lake and the Larder Lake gold areas. This belt of Temiscamingue sediments can be traced east of the interprovincial boundary into Quebec over a distance of 120 miles, paralleling to the south the northernmost transcontinental line of the Canadian National Railway.

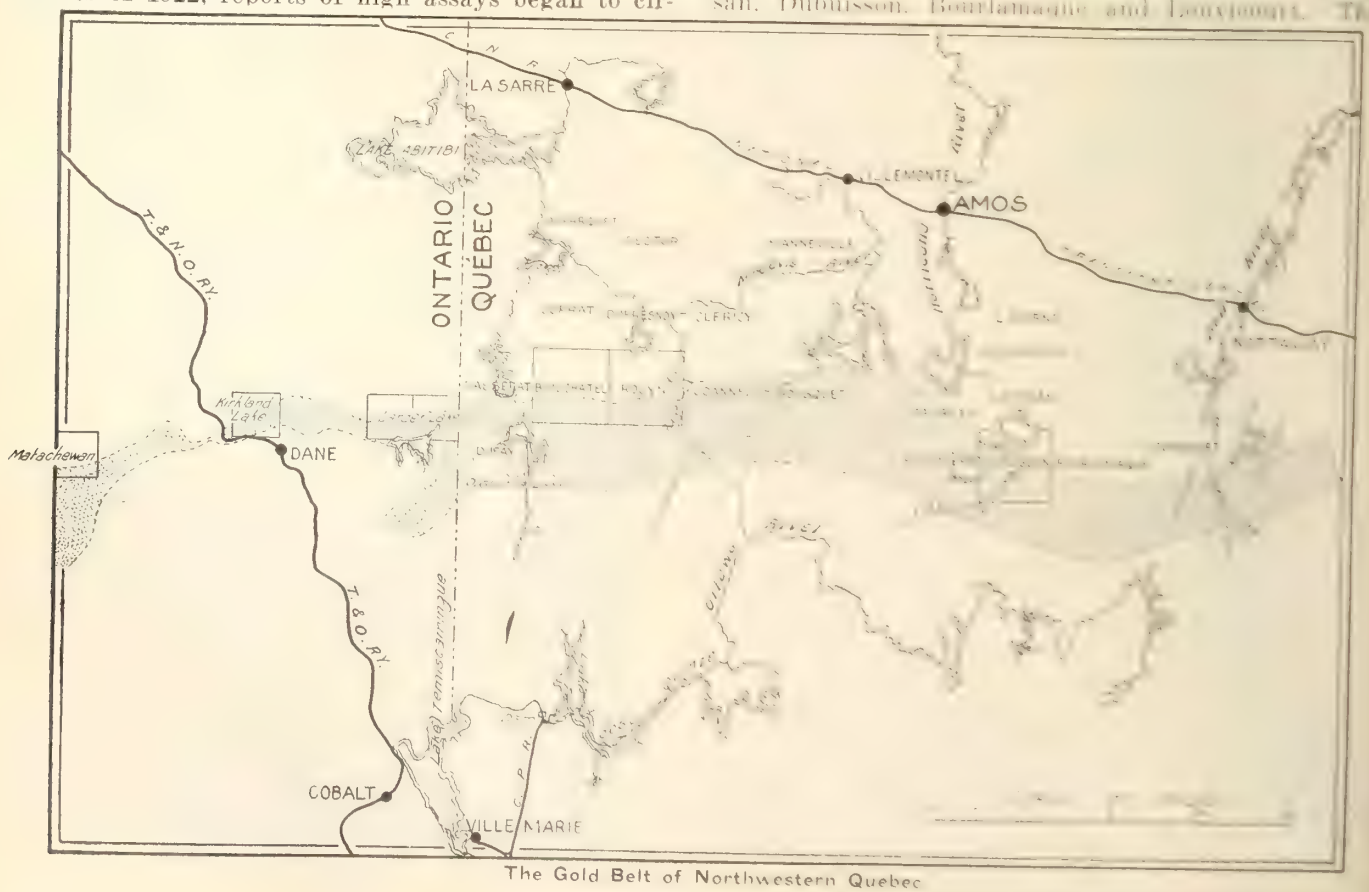
Camp of Noranda Mines, Ltd. on Héré Lake
Rouyn Township

Previous to last year native gold had been found in two places along this belt: in 1906 on Lake Fortune in Boischatel township and in 1911 in Dubuisson township. At these two places shallow pits and surface trenching were the only development work done until last winter, when more extensive exploratory work was performed. During the last twelve months Rouyn township has been the scene of much prospecting activity. The first claim recorded in Rouyn was staked on the 11th of September, 1920, in the name of E. J. Miller. In May of the following year E. H. Horne staked west and south of the above claim. In the summer of 1922, reports of high assays began to circulate and the few with "inside" information staked claims in adjoining sections, mostly in the northwestern corner of the township. By the end of the winter nearly the whole of the township had been staked, as well as large sections of adjoining townships.

On the 1st of July, 1923, the number of claims recorded was 975, covering an area of 175,000 acres in the townships of Hébécourt, Duparquet, Destor, Montbray, Duprat, Dufresnoy, Clérioy, Dasserat, Boischâtel, Rouyn, Joannès, Dufay, Montbeillard and Bellecombe. A part of this acreage has been transferred by claim holders to syndicates and to companies recently incorporated; amongst these are the following:—

Amulet Gold Mines Ltd.
Argonaut Gold Ltd.
Boischâtel Mining Syndicate
The Chance Syndicate.
Crown Reserve Mining Co. Ltd.
Dasserat-Rouyn Goldfields Ltd.
Gold Belt Company.
The Lake Fortune Mining Co. Ltd.
The Larose Mines Ltd.
Lyman-Quebec Exploration Syndicate.
Montreal-Rouyn Mines Ltd.
Noranda Mines Ltd.
M. J. O'Brien Ltd.
Pontiac Syndicate.
Rouyn Gold Mines Ltd.

Besides the above townships, other prospecting centers have developed and other groups of claims have been taken up along this same belt of Temiscamingue rocks. In all some 150 claims, of a total area of 15,000 acres, have been recorded during the year, mostly in the townships of Villemontel, Malartic, Fournière, Varsan, Dubuisson, Bourlamaque and Louvicourt. The



The Gold Belt of Northwestern Quebec

aurentian Gold Mines Ltd., Nepawa Development Syn-icate, Quebec Gold Rand Ltd., Stabell Gold Mines, Jnion Mining Corporation Ltd., have been organized o take up some of these claims.

The activities in Rouyn township are what attracted ately the attention of the mining community, owing o the fact that a considerable amount of work has al-eady been done, including several thousand feet of liamond drilling. Systematic prospecting and develop-nent work is being carried on in several places, as he accompanying photographs will prove, and the esults of sampling on a large scale are said to be con-sistent and quite satisfactory. However, the Rouyn listrict is not a poor man's camp, inasmuch as over-burden covers most of the ground and often is heavy. This makes prospecting difficult, both financially and physically, and if to this is added the remoteness of the region from the railway, and the consequent high cost of transportation of supplies and machinery, it will be realized that only strongly backed organizations are able to do more than the mere assessment work. On this account the development of the district as a gold producer may be slow, and it is possible that several years may elapse before the first gold brick from Rouyn is sent to the Mint. But there is no doubt that the gold is there. The favourable geological associations — Cobalt and Temiscamingue sediments, Keewatin volcanics, cut and invaded by gabbros, granites, syenites, rhyolites and above all by various of the much-sought-for porphyries — can be observed and recognized without any break from west of Matachewan, through Kirkland, Larder, Boischâtel, Rouyn, Dubuisson, Louvicourt, to the east of the headwaters of the Bell river.

Three geological parties sent in by the Federal Department of Mines, under Dr. H. C. Cooke, Dr. R. Harvie and Dr. W. F. James respectively are working out the details of the geology and mapping the rocks. The result of their work will be awaited with eagerness by the prospectors interested in Northwestern Quebec.

The Quebec Asbestos Industry

A General Description

By NORMAN R. FISHER*

The asbestos producing region of Canada, world famous because of the quality and quantity of the asbestos it produces, is centered in the Eastern Townships of the Province of Quebec, along a stretch of high ground known as the Notre Dame Hills, the extension in Canada of the Green Mountains of Vermont State. This high ground follows right through to the Gaspé Peninsula on the St. Lawrence and outcrops of serpentine following the same line of strike are to be found every here and there along it; but only in one section of it about 70 miles long, lying between the towns of Danville and East Broughton, does this serpentine contain asbestos in sufficient quantity or under sufficiently advantageous circumstances to justify its exploitation. Within this section there are present six producing centres, generally designated as the East Broughton, the Robertson, the Thetford, the Black Lake, the Coleraine and the Danville areas, and in each of these one or more mines are now being operated on a considerable scale.

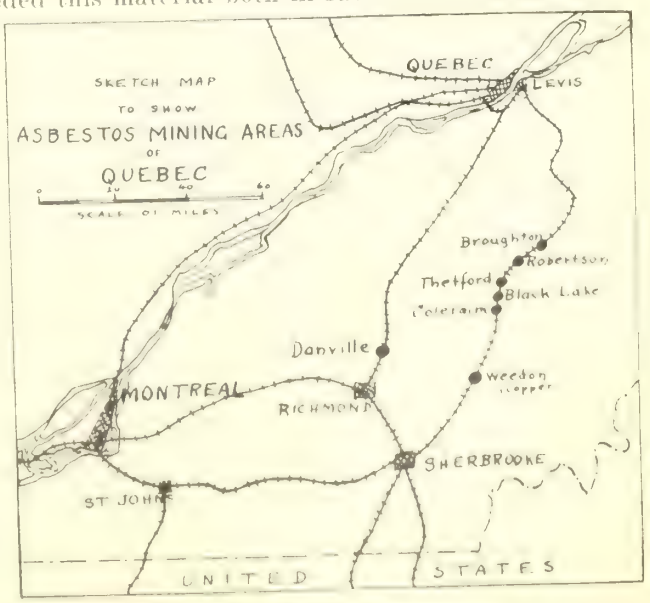
The asbestos produced in these several areas is all of the same chrysotile variety, the fibrous form of the serpentine itself, but varies considerably in quality. Each quality has, however, its particular advantages for certain manufacturing purposes; but that more desirable for spinning, which calls for the highest quality material, is almost altogether found in the Thetford area, where the asbestos is generally conceded to be the finest of its kind not only in this Province, but in any part of the world in which it is at present being produced in commercial quantity.

Johnson's Mine — the Pioneer Pit

Though the occurrence of asbestos in this section was known to the Geological Survey of Canada many years before, its actual exploitation commenced only in 1878 as a consequence of the construction of the Quebec Central Railway through the district, and even then only in a very small way. In that year, Mr. Andrew Johnson, still living in Thetford Mines and still an active operating member of the industry, made the first attempt at producing asbestos on a commercial scale, when he started a small quarry on lot 27, range 6, of the Township of Thetford within a short distance of the present Thetford Mines railway station. This small undertaking later blossomed into a large and profitable mine, later known as the Johnson's Mine, which is in active operation at the present day.

About the same time work was also commenced on an adjoining property, now known as the Bell Mine, and in the following year the King Brothers, prominent lumbermen of the district at that time, commenced opening up another outcrop close by, later to become the well known King Mine of the Asbestos Corporation of Canada.

The larger part of this went to England to be sold in competition with the Italian product then principally used, and as it proved to be of much better quality, especially for spinning purposess, it soon superseded this material both in favor and demand.



*Manager, Consolidated Asbestos, Limited, Thetford, Que.

Whether the discovery and exploitation of the Canadian asbestos at this time was instrumental in promoting the progress of the asbestos manufacturing industry, which was then only in its infancy, it is hard now to say; yet the fact remains that from then on it grew rapidly, and along with it an ever increasing demand for the Canadian product. As a consequence, the mining of asbestos in the Province of Quebec soon became an established industry, and the success of its pioneers in the vicinity of Thetford Mines induced intensive prospecting elsewhere along the serpentine belt for other occurrences of moment, with the result that within the next few years many other properties were opened up between Danville and East Broughton, several to become eventually permanently established and to continue as large producers to the present day.

Cableway Derricks at an Asbestos Pit

Milling Commenced

In the early days of the industry only the vein matter known as "crude" was recovered, this being merely hand-cobbed from the quarried rock and afterwards sorted into two or three grades according to its length and quality; and even to this day more or less the same practice is in vogue for the recovery of the longer "crude" content of the rock. Later, successful steps were taken to discover some satisfactory mechanical method by which the rock could be treated for the recovery of the balance of its asbestos content. In the course of time the method then evolved was improved upon considerably, but solely in the manner of its application, not in principle. Today there are numerous mills in active operation throughout the field, some of very large capacity, provided with as modern and efficient equipment of its kind as can be seen anywhere. Very few of these mills are working today at full capacity, yet together they are treating at the rate of about three million tons annually, for an average recovery of about 6 per cent in the form of what is known as "mill fibre."

This mill fibre, because of its comparative shortness and its more or less bruised condition consequent upon the hard treatment it has received in the course of its recovery, naturally is, for the most part, not nearly so valuable as the crude recovered by hand; yet in most instances it is now the main source of revenue.

Production Record

The accompanying table, compiled mainly from official statistics, shows the annual output of asbestos, including both crude and mill fibre, from the mines of the Province of Quebec since the inception of the industry in 1878 up to the end of last year, and is interesting as showing not only the great growth of the industry during this time, but more particularly the gradual increase, indicative of its stability. It also shows that the banner year of the industry was in 1920, when there was shipped from the various mines 179,891 tons of crude and fibre of a total value of $14,749,048 or an average value of $81.99 per ton, the highest average since 1891, when only crude was produced.

These high figures were, of course, in no small measure due to the universally prosperous industrial conditions and inflated prices of the immediate post-war period and were consequently abnormal. However, when the reaction set in the following year and deflation accompanied by great industrial depression prevailed on all sides, the asbestos industry was hit much harder than would ordinarily have been expected. In that year alone not only did shipments drop to around 50 per cent. of what they had been during the previous year, but the value per ton of what was shipped dropped over 25 per cent. Then, to make matters worse, the break in prices did not stop, for though in the following year, 1922, there was a marked recovery in demand, there being shipped from the mines in that period some 160,339 tons or the second highest quantity in the history of the industry, unfortunately the prices obtaining still continued to drop till they averaged only some $37.75 per ton for the year as compared with $81.99 per ton that ruled but two years before. The

Steam Shovel in Asbestos Pit

Glory-holes, Leading to Underground Mine Workings

higher priced crudes were naturally hit hardest, No. 1 Crude, which in 1920 was selling at around $2,500 per ton, dropping in value in 1922 to around $500 per ton, while many of the other grades suffered in proportion almost as badly.

Price-Cutting Followed the Slump

This unfortunate condition of affairs was not alone due to the general price deflation of the period but also in great measure to the price-cutting war amongst the producers themselves, induced by a too limited market, made still narrower by the smallness of the European demand, now shrunk almost to insignificance through the lack of purchasing power of Germany and Austria though but a few years before they absorbed in the vicinity of 80 per cent. of Canada's whole output.

This competition for what business remained was both foreign and local in character, the foreign competition being in long stuffs, principally the product of South Africa, which during the past few years has become a vital factor in the industry through its cheap production of an excellent quality of chrysotile crude, whilst the local competition was for the most part in short stuffs of which there was being produced by the mines much more than the market could absorb; and unfortunately there existed no coöperative arrangement amongst producers to counteract the tendency to excessive price-cutting.

Table of Annual Production of Asbestos Crude and Fibre in the Province of Quebec since the beginning of the Industry

Year	Tonnage Produced	Total Value	Average Value Per Ton
1878	50	.....	....
1879	300	19,500	65.00
1880	380	24,700	65.00
1881	540	35,100	65.00
1882	810	52,650	65.00
1883	955	68,750	72.00
1884	1,141	75,097	65.81
1885	2,440	142,441	58.37
1886	3,458	206,251	59.65
1887	4,619	226,976	49.55
1888	4,404	255,007	57.90
1889	6,113	426,554	69.77
1890	9,860	1,270,240	128.82
1891	9,279	999,878	107.75
1892	6,082	390,462	64.16
1893	6,331	310,156	48.99
1894	7,630	420,825	55.15
1895	8,756	368,175	42.04
1896	10,892	423,066	38.84
1897	13,202	399,528	30.26
1898	15,893	496,340	31.23
1899	15,571	581,667	37.36
1900	21,408	719,416	33.60
1901	33,466	1,274,315	38.70
1902	30,634	1,161,870	37.92
1903	29,261	916,970	31.94
1904	35,479	1,186,970	33.43
1905	48,960	1,476,450	30.16
1906	61,675	2,143,653	34.76
1907	61,985	2,455,919	39.62
1908	65,157	2,551,596	39.16
1909	64,965	2,296,584	35.35
1910	80,605	2,667,829	33.10
1911	102,224	3,026,306	29.60
1912	111,175	3,059,084	27.52
1913	136,609	3,830,504	28.04
1914	107,401	2,895,935	26.96
1915	113,115	3,544,362	31.34
1916	133,339	5,182,905	38.87
1917	137,242	7,198,558	52.45
1918	142,375	9,019,899	63.35
1919	135,862	10,932,289	80.47
1920	179,891	14,749,048	81.99
1921	87,475	5,199,789	59.44
1922	160,339	6,053,068	37.75
Total	2,209,368	$100,741,932	$45.60

The Occurrence of Asbestos

The geology of the asbestos-producing region of Quebec has been so thoroughly and well described in the various Government reports published from time to time that it would be superfluous to discuss it further here except in a very general way. Suffice it therefore, to say that the asbestos bearing serpentine occurs as part of a great belt of basic intrusive rocks stretching in a northeasterly direction for several hundred miles from the State of Vermont right through to the St. Lawrence via Gaspé Peninsula. Though in this particular belt serpentine is found exposed only in comparatively limited areas and intermittently throughout its length, it is nevertheless its chief economic component, and this solely accounts for the fact that the whole of it is now generally known and referred to as the "Serpentine Belt."

It has not yet been definitely established in what form this igneous belt intrudes the ancient rocks, for the most part metamorphosed sedimentaries, that enclose it; but judging from its occurrence in the Thetford, Black Lake and Coleraine areas, where it is exposed for a considerable area and where more detailed information is available concerning it than elsewhere, it would appear to occur in the form of a sill some 2,000 feet thick that has been folded steeply on a N. E.-S. W. direction.

The "Slip Fibre" Area

The serpentine of this particular area, and in fact

Stope in an Asbestos Mine

of the greater part of the belt, is massive in character and contains many acid inclusions both small and large, of a material, colloquially known as "granite" though it is really for the most part aplite that has apparently segregated from the original magma during the last phase of its cooling; but there is also another apparently quite distinct body of it, also of considerable economic importance, that is quite schistose in character and contains no such acid inclusions. This latter rock lies in a part of the Belt about 12 miles long in and between the East Broughton and Robertson areas, and a little to the north of the main body, and is, comparatively speaking, quite narrow, being at most only some 300 feet wide. It is much lighter in color and more talcy to the feel than the general run of the serpentine and contains most of its asbestos in

Cobbing "Crude" in a Stope

the form of what is known as "slip fibre" instead of the usual "cross fibre" variety of the massive serpentine.

This slip fibre is a friction product that occurs along, and more or less parallel to, the cleavage or shear planes of the serpentine of which it is merely an alteration product formed subsequent to its solidification, whereas the cross fibre variety is a solution product that occurs in the joint planes of the serpentine and was apparently formed contemporaneously with its solidification.

The slip fibre section of the Serpentine Belt is much more regular in its fibre content than is the cross fibre section, and on the whole it carries a higher proportion of recoverable fibre. The explanation of this is that while with the former the asbestos is disseminated fairly uniformly throughout the whole mass as a result of the general nature of its structural metamorphism, it occurs in the latter for the most part merely as veins, either scattered throughout it sporadically or segregated into net-works or systems of parallel veins to form enriched zones or masses, while the intervening rock often contains little or no asbestos at all, when it is known colloquially as "dry rock."

Characteristics of the Asbestos

The asbestos produced throughout the Belt is all practically the same throughout mineralogically, but varies considerably from place to place in its physical characteristics. At times it is white in color, quite soft and talcy to the feel and low in tensile strength, while again it is of a soiled, dark color, quite harsh to the feel and rather brittle; but in the Thetford area proper, where the best quality of asbestos is found, it feels and looks, when carefully distintegrated, for all the world like the finest quality of silk and can almost as readily be spun into fine yarn of considerable tensile strength. A general average analysis would approximate the following:—

Silica	40%
Magnesia	40%
Water	14%
Alumina	2%
Iron	4%
	100%

When heated, its combined water is given off slowly until a temperature of about 450 degrees C. is reached but above this it comes off readily, and the more it is driven off, the more harsh and brittle does the material become and the more does it lose in tensile strength. Its fusion point is in the vicinity of 1,530 degrees C.

Original Mining Methods

All the deposits of asbestos now being mined outcropped originally as pay ore and consequently were originally attacked directly at the surface by various open-cast methods of mining.

In some places it was possible for a time to quarry directly into the side of hills and other prominences containing the asbestos, but oftener it was found necessary to commence sinking from the start and to carry on, on a small scale, the same kind of open-cast mining now being conducted on a huge scale at many properties with great open workings several hundred feet in diameter and up to 350 feet deep.

Originally, when the pits were small, ordinary boom derricks operated by hand or horse power were used to lift the broken rock to the surface, but as they increased in dimensions and such primitive appliances became impracticable, cableway derricks were installed and steam, and later electric, hoists were introduced in order that the broken rock might be more expeditiously and economically disposed of. This was done in boxes of 1 to 1½ tons capacity, which were filled by hand at convenient points within the range of the cableway and then hauled to the surface to be dumped into waiting cars, bins or pan conveyors.

Cableway Derricks

As the pits were gradually extended laterally, additional cableway derricks had to be installed, until at times there were as many as ten or more of them installed along one great opening. As the lateral

Electric Underground Haulage

mits of these pits were reached and the convergence of the pit walls at depth ultimately rendered the further use of existing equipment impracticable, other methods of attack had to be sought and adopted. At the King Mine at Thetford Mines, an elaboration of the cableway derrick system was adopted, and by the use of much heavier equipment, derricks were installed having a span in the neighbourhood of 1,000 feet, which enabled the pit to be widened commensurately and at the same time carried to a much greater depth. This installation is undoubtedly one of the most elaborate of its kind in existence, and with the six derricks now in operation it is possible, under ideal conditions and with sufficient loaders available, to handle, with the 5-ton boxes in use, upwards of 300 tons an hour.

Travelling Cranes in Pits

At other properties, such as the Bell Mine at Thetford, faced with the same problem, a less elaborate yet quite as efficient method was adopted in the shape of travelling cranes operating on the pit bottom, which lift and dump the boxes as they are loaded by hand into 30-ton cars which are drawn direct to the surface crusher house up a haulage way with a 1 in 10 grade. This system is undoubtedly the essence of simplicity and cheapness for the particular method of mining practised, but, like other similar open-cast methods, it has its limitations in depth.

Similar practice to this is in use at several other properties in the district, while at others the only difference is that, instead of man-handling all the rock into boxes, it is excavated and delivered direct to the cars by means of steam shovels. At Danville this system is in use on a large scale with several shovels in operation. At the Vimy Ridge Mine of the Bennett-Martin Company it is practised under the unusually advantageous conditions of a hill-side operation. In the slip fibre belt its use is almost universal.

Steam Shovels

The steam-shovel method is undoubtedly the cheapest of all from the cost-per-ton point of view; but where the rock contains a considerable proportion of crude, as it does in the Thetford District, it is considered to be more profitable in the long run to man-handle all the rock into boxes so that a better extraction of the crude may be made during the process of loading. This practice also permits of an efficient separation being made at the loading stage of any associated "granite" and "dry rock" the deposit may contain, the latter being eliminated in this manner at some mines to the extent of upwards of 50 per cent. of the total rock mined.

Underground Mining

At the Thetford Mine of the Consolidated Asbestos Limited, none of the above methods were practicable, owing to boundary and other limitations, so that when the cable-way derrick system became impracticable, it was decided to attack the deposit by underground methods. A large three-compartment shaft was sunk to a depth of 520 feet and the deposit opened up from this by an elaborate system of tunnelling at depths of 200 and 375 feet from the surface, preparatory to mining it concurrently from both levels. At the junction of these levels with the shaft, large storage pockets are provided to receive the ore, which is hauled to them in trains of four 5-ton cars by storage battery locomotives. From these pockets the ore is drawn as required and raised to the surface in two 4-ton self dumping skips for storage. Each of these levels is also connected to the surface by an inclined double-track haulage way with a grade of 1 in 3, through which the underground cars may alternatively be drawn direct to the surface to deliver ore direct to the crusher house, or to take any barren rock or overburden direct to the dump.

The methods of mining in use are shrinkage stoping and glory-holing, or a combination of the two. At certain points advantageous for glory-holding, raises are run to the surface, and after any overburden in

Hoisting Ore from an Asbestos Pit

their vicinity has been disposed of through them, all the ore within their reach is shot down.

At other points in the deposit where stoping is more practicable, large 35-foot wide stopes have been developed. These are arranged in parallel with 40-foot pillars. No timbering whatever is necessary, as suitable horizontal pillars about 15 feet thick, pierced about every 20 feet for 5-foot wide loading chutes, are left above the drifts. As these stopes break through to the surface they become automatically great, elongated glory-holes into which the dividing walls or pillars are broken from the surface down.

Open Pit vs. Underground Mining

Without going into the controversial question of comparative costs, it might be said that this method of mining has many obvious advantages over any open cast method, more particularly as operations can be carried on without interruption during any kind of weather, a very important feature in such a climate as Canada's. It permits also of a considerable broken ore reserve being provided to regulate output, and of selective mining being more readily applied to control the grade treated. It is true that in this method the recovery of crude cannot be made so well directly the rock is broken as is possible with open cast methods where every ounce of rock is man-handled; but with the arrangements provided to meet this factor the ultimate recovery is every whit as good, if not better, by underground methods.

To attain this, not only is all the broken rock, both of the glory hole and stope workings, hand picked and cobbed for its crude contents, just as is done ordinarily in the pits, but it is given later a further close scrutiny as it passes over a system of picking belts provided for the purpose immediately following the primary crushers.

Crude Recovery and Preparation

The most valuable of the asbestos is the "crude." This varies considerably, both in quality and quantity, at the various pits, and in the same pit, some of it being too "lifeless" and weak to be suitable for the spinning which is its principal use, while more of it is too harsh and brittle for any such purpose.

Though crude suitable for spinning is to be found at many points throughout the Serpentine Belt, by far the most desirable for such a purpose is that recovered from the mines in the immediate vicinity of Thetford Mines, because of its exceptional fineness, flexibility and tensile strength. The veins in which it occurs vary from a fraction of an inch in width up to as much as 6 or 7 inches wide, but seldom are they over two inches wide. Only veins of ½ in. or more in width are, however, gathered by the hand picking and cobbing methods in use, and after drying on steam-heated grids it is carefully overhauled by the boys or girls under expert supervision and sorted into grades for the market. At present only two grades are made, commonly known as the No. 1 and No. 2 of the particular mines producing them. The No. 1 is the select part of the material and measures ½ inch or more in length, while the No. 2 is the discard from this after all rock matter has been removed and after it has been screened over a 4-mesh screen to remove the shorts.

The recovery of crude per ton of rock mined varies considerably, not only throughout the district generally, but at each mine. The percentage in the richer patches or zones is, of course, at times exceptionally high; but the amount recovered in terms of the total rock mined averages only from 0.15 to 0.25 per cent at properties regularly by producing crude.

Milling Methods

The object of the milling is to liberate as much as possible of the asbestos content of the rock not readily removable by hand, with the least possible separating and bruising of the resulting fibres. The existing practice is to crush the rock only sufficiently to enable special fiberizing machines to liberate its fibre content and then to extract the fibre from the rock by means of suction suitably applied.

Before the asbestos industry came into its own, lumbering was the chief industry of the district, and it is interesting to note that even to this day the hand of the lumberman can be seen in the method that was developed to recover the asbestos from its mother rock. In those days, as now, it was the practice of the lumbermen to dispose of the shavings and sawdust from their saw-mills by a system of suction from fans and to collect it in separators, and it was the happy thought of someone familiar with this practice to use it to recover the fiberized asbestos from the rock after it had been freed by some machine adapted to the purpose. This idea, once properly worked out and applied, proved to be a decided success, and though other methods, both dry and wet, have been suggested and experimented with from time to time, they are merely elaborations of this original idea, in general use to this day in all the mills. The crushing, drying and fiberizing equipment of the mills is as large and as efficient as will be found anywhere.

The practice followed by all is, in the main, the same and may be classified under the following heads:

1.—Coarse Crushing.
2.—Drying.
3.—Fine Crushing and Fiberizing.
4.—Extraction of the Fibre.
5.—Grading.

Coarse Crushing

The size of the primary crushers varies considerably throughout the field, as it is governed not only by the capacity required but by the size of the material to be delivered to them, which varies at each mine according to the method of mining used. At the Johns-Manville mine at Danville, for instance, where large capacity shovels are used, it is considered desirable to use crushers capable of taking care, when necessary, of quite large blocks of rock, so 48" x 60" sectional jaw crushers have been adopted. At Thetford Mines, where most of the broken rock has to be man-handled before reaching the crushers and therefore contains but few pieces of much size, 24" x 36" jaw crushers are for the most part found quite adequate, though a 36" x 48" size is preferred by some.

The jaw type of crusher is almost universally preferred for the primary crushing in this field, only one or two of the mines using gyratories for the purpose.

Following the primary crushing it is the practice of one of the mines, with highly satisfactory result, to pass all crushed rock over picking belts in order to sort from it whatever crude, barren rock and foreign matter can be conveniently and economically removed in this way before it passes to the mill.

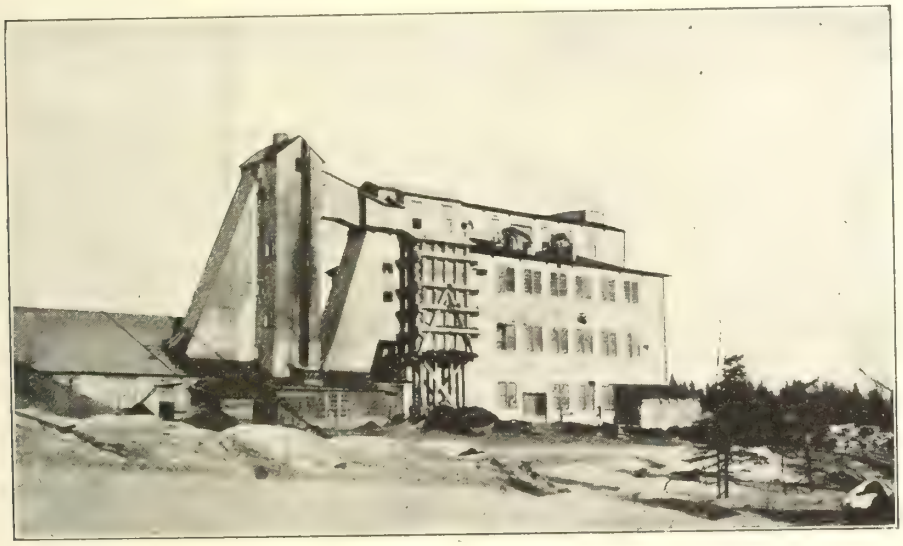
The secondary crushing equipment, though it all has the same object in view, viz., the further break-

ing down of the rock to about 2″ in preparation for drying, varies considerably throughout the district. Some mines use corrugated rolls, others jaw crushers, and others gyratory crushers for the purpose, while some use a combination of these, yet all seem to be satisfied with their respective practices and results.

Drying

Nor is there any standard practice for dryers. Many different types of these have been tried out in the district since the inception of the industry, only to be eventually discarded, till now most of the mills have a single shell, rotary type with forced draught applied under the fire box, which is sometimes installed at the charging end and at other times at the discharge end. Some of the largest operators prefer, on the other hand, the return current, internal tube, rotary type, the ore being raised to the top of the drying shaft by elevators, whence it drops by gravity over baffles, against the rising heat, to the bottom. Apart from the respective advantages and disadvantages from an operating point of view, the adoption of any type must be considered in the light of the class of ore to be handled and the condition desired at the end of the process.

After drying, the material is conveyed either direct for further treatment or to storage bins ready to be drawn upon as required.



Asbestos Mill at the Fraser Mine, E. Broughton

Ample storage facilities between the mine and the mill are, of course, most desirable in any mining operation. Under conditions such as obtain here, where the mines are liable to extended interruption through inclement weather, storage is an essential. Most of the mines have, therefore, storage bins of unusually large capacity, one of them having facilities to store as much as 20,000 tons of dried crushed rock.

Fine Crushing and Fiberizing

Once this dried material arrives at the mill proper, the process begins of extracting its fibre content. Any fibre already free is first of all removed from the rock by one of the usual suction methods. The rock is then passed to suitable comminuting and fiberizing machines to release from it the fibre it still contains in rock-like form.

It is the practice of some mills to treat this rock first in purely crushing machines, and then to pass it into one of the many types of fiberizing machines available for the purpose. Others do the breaking down and fiberizing concurrently in machines designed for the combined purpose. In the former practice gyratories, disc crushers or rolls, or some combination of these, are used to break down the rock which is then passed into the fiberizing machines, of many varieties such as cyclones and jumbos. In the latter practice the material passes direct to hammer mills either equipped with, or without, sizing grids, in which the crushing and fiberizing are done simultaneously. The resultant product of these is first passed under suckers to remove its freed fibre content, and is then passed to cyclones or jumbos, or both, for further treatment to free what fibre still remains.

After each operation the rock thus treated is passed over screens or through specially designed gravity apparatus to facilitate the removal by suction of its released fibre content, which is subsequently collected in separators, which collect it by centrifugal action.

The fibre recovery varies considerably from mine to mine according to the class of rock being treated and the grading that is practised. For individual mines it ranges from about 3 per cent. up to 15 per cent. or more; but the average for the whole field is about 5 per cent. of the rock mined and 6 per cent. of the rock milled.

Grading

The fibre thus collected is then treated on vibrating or rotating screens known as graders, by which it is cleaned and graded as required, ready for the market.

The grading is regulated by test in a testing machine that has been evolved for the purpose and adopted as a standard for the whole district. It consists of a nest of three trays or boxes, the top of which is equipped with a screen having a half-inch opening, the next with a 4-mesh screen, and the bottom with a 10-mesh screen. All are so fixed in the machine that they can be shaken together at 300 revolutions per minute with a horizontal stroke of 1½ inches and automatically stopped at the end of two minutes, the usual period of the test.

To test any grade of fibre, 16 ounces is measured and placed on the top tray and then shaken for the usual two-minute period when the quantity that remains on each screen is weighed separately to give the final test. By means of this machine the fibre is graded into the particular grades desired and is then bagged ready for shipment to the manufacturer.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

THE RECORD OF COBALT, PORCUPINE AND KIRKLAND LAKE

(by our Northern Ontario Correspondent.)

Cobalt

A good deal of interest is being manifested in the visit of the members of the A. I. M. M. E. to the Northern Ontario camps, and the local managers are making preparations to give their guests an interesting time. Two days will be spent in Cobalt and the vicinity, and although the Cobalt of to-day is very different from what it was a few years ago, it is still the most important silver camp in the country. Discovered twenty years ago, the extraordinary richness of the deposits gave the impression that it would be a very short-lived camp; but to-day, although its production is far below the peak, engineers hesitate to place any limit on its life, and the chances are the camp will still be producing at the end of another twenty years. The original discovery was La Rose, and to date from a comparatively few acres on this claim 20,000,000 ounces of silver have been produced. In 1905 the boom really started, and the camp rapidly grew in size and importance. In 1911 there were approximately 25 producing properties and in that year the output was about 32,000,000 ounces, and the few square miles comprising the camp was the third largest silver producing community of the world, being exceeded only by the whole of Mexico and the whole of the United States. From 1911 on, the production of the camp gradually declined until at present it is approximately 8,000,000 ounces a year, with seven companies producing.

Most of the production of the camp has come from the conglomerate of the Huronian series and from very shallow depths. Of the 20,000,000 ounces produced from La Rose claim, practically the whole came from within 100 feet of the surface. These shallow veins are becoming exhausted, but new possibilities are being opened up on the lower diabase-Keewatin contact, which throughout the larger part of the camp remains unexplored. Near the north end of the camp extensive exploration on this contact is being undertaken by La Rose and Continental, while in the Southeast part of the camp exploration on the lower contact will be undertaken on the Beaver at a depth of 1,200 feet. If these efforts are successful, (and La Rose is already producing substantial quantities of silver from this area), it will give a great impetus to further exploration, which may have a very important bearing on the future of the camp.

To date the camp has produced over 330,000,000 ounces of silver, and has paid out over $95,000,000 in dividends. Among the largest producers and dividend payers is the Nipissing, the most important silver mine in the world, with over $25,000,000 in dividends to its credit. The Coniagas was the most productive single forty acres in Cobalt, with an output of over 30,000,000 ounces and dividends of over $11,000,000. Kerr Lake has paid about $10,000,000, La Rose $7,500,000, Crown Reserve $3,000,000, McKinley-Darragh $6,000,000, Mining Corporation $6,000,000, Buffalo $3,600,000, Temiskaming over $2,000,000 and Hudson Bay $2,000,000.

Cobalt is also an important source of cobalt metal, and the smelters treating the ores from this camp practically control the world's market for cobalt and its salts. An other important by-product from Cobalt ores is arsenic, which is so largely used as an insecticide.

Power for the camp is supplied by the Northern Ontario power company, which both generates electric power and makes compressed air. The compressed air system, which is known as the Taylor Hydraulic System, is a unique installation and is the largest natural air compressor in the world, with a capacity of 44,000 cubic feet of free air per minute. The flow of the Montreal river is diverted into two shafts, the tops of which are fitted with an adjustable casing filled with 14-inch pipes. The falling water sucks the air down with it and this air is released in a large drift 1,000 feet long, with a collecting chamber above it. The water passes up through the outlet shaft, which is about 265 feet deep and whose depth governs the air pressure. The air is drawn off from the collecting chamber and transmitted to Cobalt, a distance of 9 miles, through a 20-inch pipe line, and from this a series of smaller pipes distribute it to the mines.

The Cobalt district, in addition to the importance it derives from its own production, has also contributed to an important extent to the development of other mines and mining districts. Money derived from Cobalt mines has helped to finance properties in South Lorrain, Gowganda, Kirkland Lake, Porcupine and many other places.

Porcupine

Porcupine was discovered in 1910, the largest mine there being the Hollinger, which was financed largely by money derived from Cobalt. The purchasers of the Hollinger were the Timmins-McMartin-Dunlap syndicate, who were also the original owners of La Rose. After working the latter property for a time and making a profit of $1,200,000, they sold it for $5,000,000, so that when they purchased the Hollinger they were well able to finance it to a producing basis.

The new camp passed through a great many vicissitudes. Transportation in the early stages was difficult, as the camp was 30 miles from the railway. Both Hollinger and Dome, however, went ahead with mill construction, hauling most of their supplies in over the winter roads. In 1911 a branch railway line was built, but just before its completion the newly constructed Hollinger mill was burned. In the summer of 1911 the Dome mill was almost completed when disastrous forest fires destroyed practically the whole of the Porcupine camp. Undismayed, the operators again began construction and in March 1912 the Dome mill was completed and put in operation. The recovery of gold for the first year averaged $13.41 a ton, a figure that has not since been equalled until the present year. Even then, many years of difficulty were ahead of Porcupine. Operations were just nicely going when the war broke out, and with shortage of labor and constantly mounting costs, production was curtailed and some of the properties were forced to suspend work entirely. After the armistice, labor was still scarce and costs high until 1921, when conditions changed. The future, for the first time in years, looked very bright, when progress was again halted by shortage of power. In 1922 the worst power shortage in the history of the northern mining districts was experienced, but despite this fact, Northern Ontario gold production amounted to about $20,000,000, or 80 per cent. of the total for Canada

Porcupine is just getting into its stride and already is one of the big gold camps of the world. Hollinger is near the top of the list of great gold mines and is producing at the rate of about $1,000,000 a month. The mill is treating approximately 4,600 tons a day, and the company proposes to increase this to 8,000 tons daily. To ensure an adequate power supply the company is developing 20,000 horsepower on the Abitibi River.

The McIntyre has had the most interesting career of any of the Porcupine mines. In 1912 it had a 100-ton mill with hardly enough ore to feed it, and sometimes not enough money to pay for supplies. Evading creditors was, in those days, almost an actual physical exercise Ten years later it had a 1,000-ton mill, and also the brightest future of any of the mines. Present production is $300,000 a month from the 1,000-ton mill, which will shortly be increased to 2,000 tons. Plans for a 5,000-foot shaft and a 5,000-ton mill are being considered and predictions are made that within five years its production will surpass even that of the Hollinger.

The other big mine of Porcupine is the Dome, which has a 1,200-ton mill and is producing about $400,000 a month. Starting off as a high-grade mine, it gradually developed into a very low-grade one and was at one time treating about $4.00 ore. Below the 6th level better ore was encountered and at present it is the highest grade producer in camp, with an average recovery of over $13.00.

Kirkland

Kirkland, unlike Cobalt and Porcupine, never had a real boom. Its development has been more gradual, and while its output is small as compared with Porcupine, it is one of the important gold camps of the continent, and that with its history still mostly to be made. Original surface discoveries were small and bore very little relationship to the important ore-bodies found at comparatively shallow depths. The original discovery was the Tough-Oakes, which produced exceedingly rich ore at the beginning. A mill was built and dividend payments made, but the company fell on hard times and the property was closed for several years. Active development was again started by new English owners and the property holds out promise of being again a profitable producer. The Teck-Hughes had a disappointing early history and was under option to several different companies. Only within the last couple of years did it really begin to forge ahead and it is now the highest grade producer in Canada, with an average of approximately $30.00 a ton, and a monthly recovery of about $100,000. The Lake Shore, with a 60-ton mill, is averaging about a $23.00 grade, mostly from development. A 300-ton mill is now being built, which the company expects to have operating this fall. The Lake Shore has been brought to its present position by the individual efforts of the original staker, and is one of the few instances where this has occurred. Another important producer is the Wright-Hargreaves, with a 200-ton mill and an output of about $75,000 a month. This mill is also being enlarged to bring it up to 400 tons a day capacity. A good deal of development work is being done in other parts of the camp, which will probably result in other properties being brought to the producing stage.

ASBESTOS IN TRANSVAAL

Reports emanating from Johannesburg describe a large deposit of asbestos from which, it is asserted, mining by steam shovel will produce short grades of fibre at a cost of 1 shilling a ton. It is 35 miles from the railway, and a branch line is said to be contemplated by the American investors interested.

NORTHERN ONTARIO

Kirkland. — The progress being made in the Kirkland Lake field is indicated by a production of $1,500,000 in the first six months of the current year, thus setting up a new production record for the camp. The largest contributor was the Teck-Hughes, with an output of about $575,000. from ore with an average grade of about $30,00. The Wright-Hargreaves produced $420,000 and the Lake Shore $295,000. During the month of June the Lake Shore produced 1,950 tons and recovered $57,198, or an average of $29.34 a ton, which constitutes a new record for the mine. The company has declared a dividend of 2 per cent payable August 15th to shareholders of record August 1st. Good progress is being made in the additions to the mill, which will bring it up to a capacity of 300 tons a day. Development work is now being carried on at the 800-foot level and this work will add materially to the ore reserves. The Wright-Hargreaves is also making additions to its mill to bring the capacity up to 400 tons a day. A mucking machine has recently been installed underground in order to handle the increased tonnage without increasing the labor force. The Kirkland Lake Proprietary is carrying on the most extensive development scheme in its history and is doing approximately 800 feet of drifting and crosscutting a month on the three lower levels at the Tough-Oakes mine. The surface equipment and the mill have been put in shape for operating, and if this development work gives satisfactory results, it is expected the mill will start running before the end of the year.

Porcupine. — At a recent meeting of the Porcupine Gold fields Development and Finance Company, held in London, it was announced that the company had taken over the share capital of the British Porcupine Development Company, which is now being liquidated. The taking over of these assets will entitle the company to options on a large number of shares in the Canadian Gold Mines Corporation, which is developing the Rochester property in Porcupine. The Rochester shaft has reached a depth of 425 feet, and a short distance lower down a station will be cut and cross-cutting started. The company has arranged for its consulting geologist, Dr. McLaren, to investigate several properties in British Columbia..

The Schumacher Mines is making a final distribution of 16 cents a share from the money received from the sale of the company's properties to the Hollinger. The Hollinger's central shaft has reached a depth of 1,700 feet. The Hollinger is now treating 4,600 tons a day, which is a record in the history of the mine. New machinery is being installed which will result in the tonnage being gradually being brought up to 8,000 tons a day. There is plenty of power available and it is stated that there is a surplus of approximately 5,000 h.p.

The McIntyre proposes to increase its present mill to 2,000 tons a day. This increase can be brought about with a minimum of new equipment. By installing another 8-foot Hardinge mill there will be plenty of grinding capacity, and by installing filters to permit of a shorter tank treatment, there will be enough tank capacity.

Cobalt. — The Mining Corporation has taken an option on a group of claims in the Gillies Limit, on which it is proposed to sink a shaft to a considerable depth. Among the properties optioned is the Burke claim, on which a small showing of silver was found some months ago. The silver showing, in itself, was very small, but the geological conditions are favourable and a real effort will be made to develop these properties. The most extensive work done on the Limit to date has been on the Provincial, Wyandoh and Waldman, all of which produced silver, but not in large quantities. The work proposed by the Mining Corporation will be the most extensive ever done on any properties in the Limit that did not have considerable surface showing.

During the first six months of the present year the Nipissing's production had an estimated net value of $1,100,767, which is in excess of the corresponding period of the preceding year. The output amounted to 1,675,000 ounces, which is an average of about 275,000 ounces a month.

Gold Strike in McNeil Township. — Last June gold was discovered in the Township of McNeil, near the Matachewan district, by Indians, and this has resulted in a rush to this district and the staking of a large number of claims. Some coarse free gold has been found in small quartz stringers, cutting the porphyry. It is doubtful if the surface showings indicate a commercial ore-body, but there is a strong possibility that a sufficient concentration may be found to give commercial values over mining widths. This chance will be enhanced if it is found that the porphyry, as well as the small veins, carries values. An option on the original discovery has been taken by a Toronto syndicate, headed by W. E. Segsworth.

BRITISH COLUMBIA

Britannia. — The Britannia Mining & Smelting Co., Howe Sound, is reported to have mined 75,000 tons of ore during the month of July. Their plant at Britannia Beach, substantially increased in size and brought up-to-date in every particular, is working at capacity. Some 500 men are employed underground. The management continues its policy of prospecting and developing new ground while extracting the ore already blocked out. Entirely new ground is being prospected in the Indian River District back of the present workings.

Stewart — It is announced that Samuel I. Silverman, of New York, has acquired the interest of W. R. Tonkin in the Fish Creek Mining Company, control of which is held by the American Mining & Milling Co. The latter Company has purchased the Georgia River Group of mineral claims, sixteen miles south of Stewart on the Portland Canal, thus giving them three properties, viz., the Fish Creek, the Betty, and the Georgia. On the Georgia stripping already has started and the ore-body is reported to have been sampled with gratifying results.

The Indian Mines Ltd., operating in the Portland Canal District, is being wound up and re-organized under the name of the Indian Mines Corporation Ltd., the latter having a capitalization of $3,000,000. The purpose is to take over a number of adjoining properties which, in the judgment of G. D. B. Turner, the managing director, and his colleagues, are essential for the development of the mine. R. B. Lamb, mining engineer, was a recent visitor to the property. Montreal and Toronto capital has become largely interested.

Good Field for Prospecting. — Mr. George Clothier, who has been on a brief visit to Victoria to consult with the Hon. Wm. Sloan, Minister of Mines, in regard to road and trail construction in the northwestern section of British Columbia, which he represents as Government mining engineer, is much interested in the opening up of the territory east and north of Portland Canal drained by the Unuk, Stikine and Iskut rivers. He has completed a trip through parts of this region and is more than ever confident that it is a field of promise from the viewpoint of prospectors. Difficulty of access is its present handicap. It can be reached by topping the Salmon river glacier or by travelling up the Unuk River from Burroughs Inlet, Alaska. The practical method would be the construction of a road through Alaskan territory to the Canadian boundary and the continuation of this road some distance into the little explored district. With such a main artery it would be possible, as the need arose, to open the country with branch trails. To carry out this comprehensive proposal the co-operation of the Alaska Road Commission is required and it is understood that representations along this line are to be made to that body. The B. C. Department of Mines, it is said, would be prepared to do its part if assured of the assistance indicated from the American authorities.

(Editor's Note — Owing to lack of space further correspondence from British Columbia, Alberta and Nova Scotia is unavoidably held over.)

FOR SALE

Entire Equipment of our Concentrating Plant at Black Lake, Quebec

including:

Three (3) Gould Triplex Pumps
Two (2) Hardinge Mills
Two (2) Farrell Crushers
Two (2) 24" Duplex Callow Screens
Two (2) Dorr Slime Thickeners
Ten (10) Deister Concentrating Tables
Two (2) Wilfley
and much miscellaneous equipment

Apply Mutual Chemical Co. of America, Black Lake, P. Q.

Advertisements other than "Employment Wanted" or "Employees Wanted" will be inserted in this department at the rate of 20 cents per agate line (14 agate lines make one inch). $2.80 per inch, each insertion, payable in advance. Space measured from rule to rule. When four or more consecutive insertions of the same advertisement are ordered a discount of 25 per cent. will be allowed.

Advertisements of "Wanted Employment" or "Wanted Employees" will be inserted at the rate of two cents a word, net. Cash must accompany order. If box number is used, enclose ten cents extra for postage in forwarding replies. Minimum charge 50 cents.

POSITION WANTED — A Canadian Mining Engineer graduate of Canadian University, specialized in the geology, development and operation of iron mines on a large scale in the Western States, desires to return to Canada to follow up the iron industry. Can give best references. Apply Box 602, Canadian Mining Journal, Gardenvale, Que.

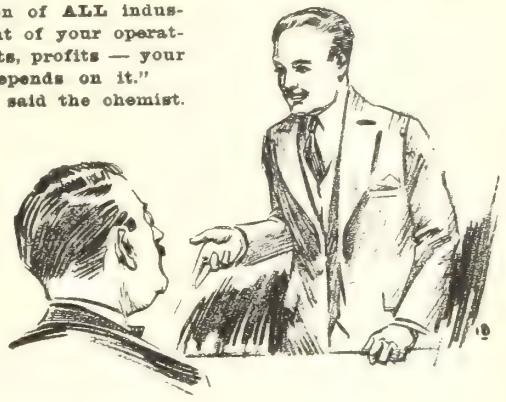
"CHEMICAL KNOWLEDGE

is the foundation of ALL industry. The amount of your operating expense, costs, profits — your very success, depends on it."
— said the chemist.



"Show me,"

said the manufacturer, "just how our business is materially benefited by chemistry.'

And the chemist did. He also told how the National Exposition of Chemical Industries presents vital information in a graphic way regarding quality, cost, preparation and treatment of all raw materials — woods, metals, glass, paper, rubber, textiles, etc., how modern machinery lowers costs and increases the productivity of labor; how material ordinarily wasted can be used to great advantage; in brief, the chemist showed how a visit to the exposition helps **any executive** to add to the profits of his concern. Preparations are under way to make America's most important Industrial Exposition this year epochal in its character and scope.

NINTH NATIONAL EXPOSITION of CHEMICAL INDUSTRIES

Sept. 17th-22nd, 1923

Grand Central Palace, New York

This exposition will furnish you with a wealth of ideas and facts about plant management, which will contribute immeasurably to your success.

Graphite, by H. S. Spence.

Gas Producer Trials with Alberta Coals, by J. Blizard and E. S. Malloch.

The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the developing of the general mining industry of Canada:—

Fuel Testing Laboratory.—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.

Ore-Dressing Laboratory.—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.

Chemical Laboratory — Analyzing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.

Ceramic Laboratory.—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.

Structural Materials Laboratory.—Experimental work on sands, cements and limes is also undertaken.

Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to **The Director, Mines Branch, Department of Mines, Ottawa.**

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson, Deputy Minister*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387
	Dividends.		

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

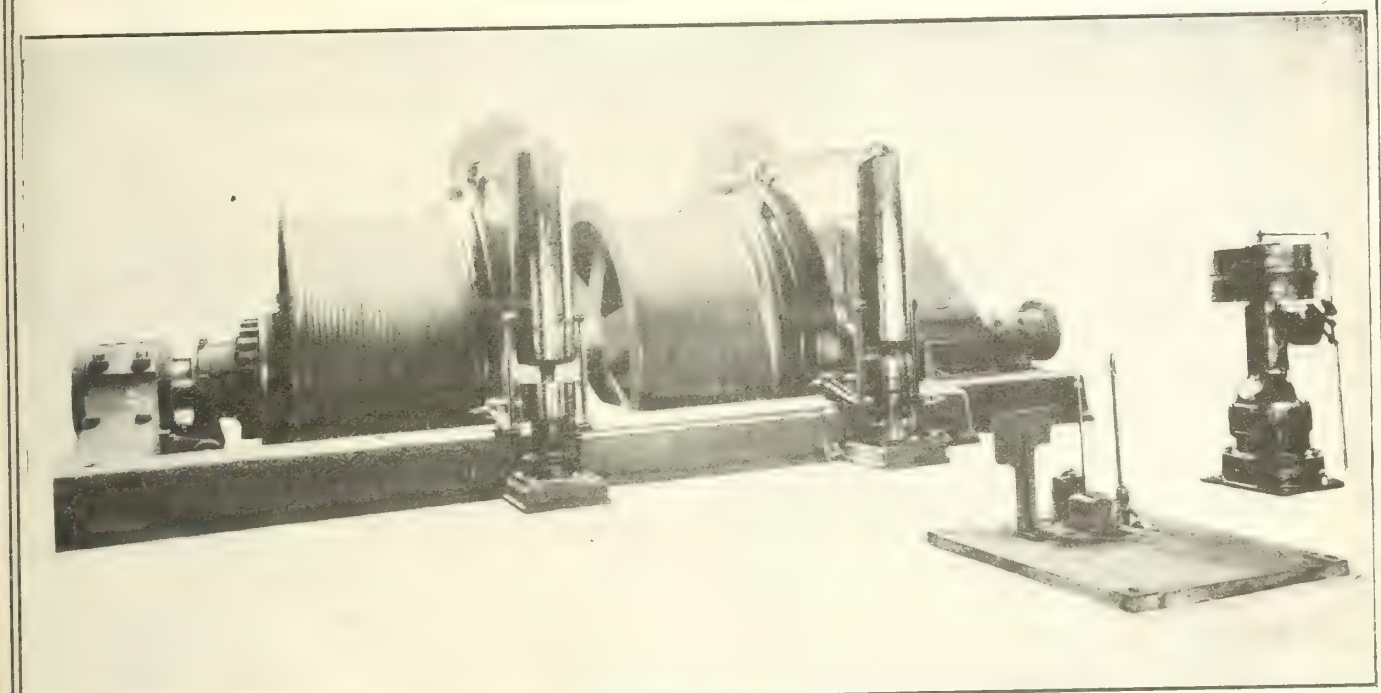
"Ottumwa" Hoists
Built in Canada



This Hoist hauls a 15 Ton Load on a 45° Slope at 1600 ft. per minute. Drums 107" Dia. by 50" face. 1¾" Rope. Driven by 900 H.P. Motor Through Single Reduction Herringbone Gears. Clutches and Brakes Oil Operated.

One of several exclusive features of the "OTTUMWA" Hoist is the PROPORTIONAL PRESSURE CONTROL for power operated brakes. Successive positions of the hand levers give definite and increasing increments of braking effect. A simple and reliable device which effectively replaces the usual complicated gear with superior results. Has proved its worth on many installations.

Link-Belt Silent Chains driving ball mills at the Utah Cons. Mining Co., International, Utah

Efficient Power Transmission

In the new mill of the Utah Consolidated Mining Company, every piece of machinery or equipment installed was of a known and thoroughly tested type. Link-Belt Silent Chain, therefore, found a place wherever conditions of extreme severity prevailed.

Link-Belt Silent Chain Drives have proved efficient under the most adverse conditions. Many of these drives have been in daily and eminently satisfactory service since 1900.

Send for Data Book No. 125. It is a handbook on silent chain practice—not a catalog. It shows how to figure drives and determine prices. Return the coupon.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387
	Dividends.		

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

A TIP TO TEACHERS

The mining engineers of today in Canada have been rained to become the servants of corporations. The echnical training in our mining schools is still di-ected to this end almost exclusively. The field for employment for such technically trained men is lim-ted, and now is about filled. The schools are turning out graduates of this type faster than employment an be found for them in mines and mills. The min-ng industry needs the services of these men in other ines of work. The curricula of our schools should be altered to suit this need.

These are conclusions to which we have come after much thought. They may represent rather an extreme view of the case; but we are confident they point in the right direction.

Canada is pre-eminently a land of undiscovered possibilities, particularly in the field of mining. In other lines of human endeavour it is becoming the vogue to an increasing extent to turn the forces of technical training in the direction of fundamental progress. The agricultural colleges are seeking breeds of wheat that will resist rust, and are gradually developing cattle that will give more milk and butter or better beef. The electrical industry employs corps of physicists and chemists, fresh from the colleges, in pursuing the unknown. The insurance companies have made their business safe by using calculations in the higher mathematics. Banks are commencing to require a period of scholastic preparation on the part of their responsible employees. Mining education in Canada is well designed to equip a young man for managing a mine or mill; but what does it do to point him towards the undiscovered treasures of mineral that must be found before mine and mill are possible?

To find payable ore-deposits and to bring them to the stage of production is, as we see it, the crucial problem of Canada's mining industry today. Heretofore it has been left almost entirely to the attention of self-trained prospectors, and to chance. True, there have been attempts to bring to these prospectors the aid of modern science, namely by way of an elementary knowledge of the minerals and the rocks. The assistance thus rendered the prospectors has been so remarkably fruitful that it is extraordinary that there has been no systematic attempt to tackle the problem the other way round, by turning the technically trained mining man into a prospector.

There have been, of recent years, a sufficient number of instances where technically trained mining men have taken up first-hand prospecting as their professional work to show that it is entirely feasible. In fact the "scouts" of a number of mining companies and syndicates have, in some cases, turned from the doubtful habit of passing on other men's "shows" to making finds on their own account. Some employers are coming to realize, still only dimly, we fear, but with growing clearness, that it is more profitable to keep a well qualified man continuously at work prospecting in a likely field than it is to have him travelling hither and thither, spending most of his time on train and trail.

More important, though, is the number of young mining men, still only a handful, who are prepared to risk their time and effort in first-hand exploration and development. A generation ago these men would have put up a shingle and waited for business; today they are "rustling" business.

It is in this direction we believe, that our mining schools should attempt to point a large part of their graduates. In this direction lie hard times, and effort above the ordinary; but the goal is success such as is far beyond the reach of him who remains a corporation's servant. We need more technically trained prospectors. It is a promising field for young men, and will remain so for a generation or more to come. The teachers in our mining schools can help to fill this need.

THE MINORITY WINS

During the first three months of this year we discussed in these pages the affairs of the Canadian Institute of Mining and Metallurgy at some length and from different angles. Our conclusion in general was that, though its members include men of first-rate ability and many whose talents could make it an active, national institution, it remains in a nutritional state. We pointed out that "what the Institute lacks at present is worthy and adequate objects upon which to expend its energies."

The August issue of the *Bulletin* contains information that corroborates this view. At the last annual meeting, in Montreal, it was proposed by a group of members in British Columbia that the by-laws be so altered as to change the requirement for membership to include strictly technical qualifications, and that those interested in the mining indus-

try but lacking these technical qualifications be classed as associate members. The proposed "member" class would, then, include the present "professional member" class, while the proposed "associate member" class would include all others except students. The amendment, submitted to all members by latter ballot, has passed by a vote of over three to one, and now is incorporated in the by-laws.

The avowed object of the western members who sponsored this by-law and whose concerted action has won the day is to make membership in the Institute mean more than it does at present. In this they have our hearty support, though we would have pursued the same object in a different way. They have demonstrated the fact that a small minority, actively interested in Institute affairs, can outvote the remainder of the members. The Secretary records the fact that of 1218 ballots sent out, but 344, or 28.2 per cent. were returned, and that of these, 260, or 75.6 per cent., were marked for the adoption of the amendment. From the fact that, at the annual meeting, where no western members were present, the amendment was opposed unanimously, we would judge that eastern members have failed to cast their ballots. Thus the westerners deserve the privilege of imposing their will on the majority.

We are confident that the active minority who thus have demonstrated their power in the Institute will use it wisely. Their first move has been to alter the status of membership in such a way as to make it more significant of professional ability. This, however, is merely the means to an end, the ultimate object being to induce activities that are fully worthy of the attention of a national Institute. When such activities shall have been inaugurated, then we shall no longer have the pitiable record of eight hundred, or over seventy per cent. of the members, not sufficiently interested in their Institute to record their votes on a vitally important by-law. With all the members so actively interested as the westerners now are, the Institute will become the worthy representative of Canada's mining industry ,which at present is attracting attention throughout the world.

THE LAKE FORTUNE FIND

It seems as if the fortunes of the gold district in northwestern Quebec, which appeared to be waning, have been made. The discovery of a new and phenomenally rich vein on the shore of Lake Fortune, which we record on another page, will, unless there is an unforeseen diminution of values underground, soon be developed into the province's first successful gold mine. The discovery will lend renewed energy to those conducting the search elsewhere in the field.

Since its discovery in 1906, the property on Lake Fortune has been subject to a series of misadventures. Enough money has been raised in its name to make a good-sized mine and erect a modern mill. Only a fraction of the money was spent on the ground, however, and most of this was badly misapplied.

In spite of the dubious history of the property, Messrs. Alderson and MacKay took it in hand last spring, ready thus to spend their money principally on a favourable report made years ago by Mr. John A. Dresser. Their faith has been rewarded, and, along with Messrs. Goyer and Bonner and their associates in Montreal, they will recoup themselves handsomely for their investment. The shares of the Company are closely held and, needless to say, there will be no stock-jobbing and no "rigging" of markets. The property at last is in competent hands, and Mother Nature will be forced to disclose her treasures by the shores of Lake Fortune.

THE ALBERTA GAS FIELDS

No important oil-field has been found as yet in the Canadian West; but the search for petroleum has disclosed resources in natural gas whose importance is scarcely realized by the generality of Canadians. We have in progress in these pages a series of articles by Mr. Newton W. Emmens of Vancouver, describing these resources in natural gas and their uses. Ordinarily we consider gas as merely a source of heat and power. This natural gas can in many cases, be made to yield gasoline, carbon black and the rare gas helium. The decision of the Imperial authorities to subsidise an airship service would appear to make the commercial production of helium an economic possibility for the near future.

The hectic search for "gushers," with their prospect of a huge and immediate return for a comparatively small investment, has tended to obscure the potential value of the gas resources tapped during the progress of the search. The fact that the search for oil is still being carried on systematically by well-informed investors such as the Imperial Oil Company is sufficient to demonstrate that the vast petroleum-bearing areas of Alberta and the MacKenzie River are still promising fields for prospecting. A point noted by Mr. Emmens is that the systematic development of the gas fields for commercial use is quite as likely as not to disclose oil "pools". After all, only scattered wells have been drilled as yet in any but a few restricted localities. The more intensive search induced by the commercial development of the fields for gas may be just what is required to find the liquid petroleum.

Meantime steps have been taken to recover from some of the natural gas in Alberta the "natural gasoline" it contains. This will give a respectable annual production of motor fuel in the province that we hope will in the not far distant future provide Canada with all, or a large part of, her requirement of petroleum products.

THE NEW MINISTRY AND MINING

The creation of a separate Ministry of Immigration n Ottawa is highly satisfactory. The problem of im- nigration is far too important to be grouped with the)epartments of the Interior, Mines and Indian Affairs nder one minister. Capable and hard working as he s, we could hardly expect Mr. Stewart to give ade- uate attention to all these departments. He will ow have more time to devote to the Department of Mines, in which we are more particularly interested, s we believe he is himself.

We hope, however, that this separation of the De- artments of Mines and Immigration will not tend to bscure their intimate relationship. As we have ointed out on many occasions in these pages, the roblems of mining and of immigration and settle- nent are much more intimately connected than most f us realize. For instance, how many farmers would here be today in the Clay Belt along the Temiskaming nd Northern Ontario Railway had it not been for he silver mines of Cobalt and the gold mines of Por- upine and Kirkland Lake? These mining operations ave induced a settlement of the land, still growing pace, that will long outlast the mines.

We ask Hon. Mr. Robb, the new Minister of Immi- gration, to remember that mining, and particularly gold mining, is his best immigration agent.

JOINT INDUSTRIAL COUNCILS

The labour problem, always a serious consideration, is doubly so in the average mining community, cut off from the remainder of civilization and usually lack- ing in those artificial attractions upon which the modern workman has grown to depend for diversion and relaxation. Today we print a brief account of how the problem is being handled at Anyox, British Columbia, written by Mr. F. M. Kelley, secretary of the Anyox Community League and welfare officer for the Granby Company in the communities centred round their mine and smelter on Granby Bay.

Our Nova Scotia correspondent mentions also today the fact that the workers of the steel plant at Sydney have accepted the proposal of Mr. Bischoff, superintendent of the plant, that a joint industrial council be formed, somewhat like the Whitley councils that have proved so successful in England. The gist of the idea, here as at Anyox, is that the men shall, through elected representatives, manage their own community affairs, and that when these affairs concern also the Company, representatives of the latter shall join in the deliberations.

On numerous occasions we have alluded in these columns to the fact, denied by no thinking man, but acted upon by few, that the ordinary relations of workers and their employers in this country, as in the other English-speaking countries, is anomalous. We profess to be democratic, yet we persist in retaining the mediaeval attitude between master and man. Indeed we have lost much that was admirable in this attitude during past centuries, for the master has ceased to care for his man and the man has ceased giving willing and faithful service in return for this protection.

Gradually the democratising of industry is being effected. There are already in Canada some notable examples of successful industrial councils in works or organizations employing large numbers of men. The scheme is working famously at Anyox, which now is known as a real, good place to live, in spite of its isolation. A number of Canadian mining men will remember the fine community spirit, developed by similar means, at the old Helen Mine in Michipicoten, north of Lake Superior, which had only dog-team connection with the outside world during the winter months. Now comes Sydney with a somewhat similar problem for solution. We are confident that the principle of democratic rule, applied in this case as in the former cases, will prove to be similarly successful, and conducive both to the financial benefit of all concerned and to a more rational mode of living.

THE A. I. M. M. E. EXCURSION

Mr. E. P. Mathewston, the genial and capable President of the American Institute of Mining and Metallurgical Engineers, brought a merry company with him to Toronto on Monday morning of this week, where he was greeted by a section of our Canadian forces under the leadership of Mr. John A. Dresser. One would hardly have guessed that these holiday-makers, gathered from every State in the Union, represent the leadership in the mining industry of the greatest mining country of the world. They have come to Canada for a two weeks' trip with a serious intention; but this intention is not going to spoil their fun.

Hon. Charles McCrea is to accompany the excursion while it is in Ontario. Already he has taken occasion to reiterate, in somewhat more definite terms than formerly, the intentions of himself and his confrères in the new Provincial government with regard to the mining industry. We are pleased to note that they have in mind the abolition of the special tax on the nickel industry.

This close companionship of several hundred of the leading mining men of the United States and Canada in their tour of Canada's principal mining area is bound to have consequences of prime importance. The good fellowship engendered will always remain a mutual asset. The friction of mind on mind during the technical sessions will advance the respective sciences. The representatives of capital will see our Northland with a new vision. The days of travel through a vast region where only narrow strips of ground have been prospected will surely stimulate an active interest.

The excursion is off to a good start, and will wind up in a brilliant finish.

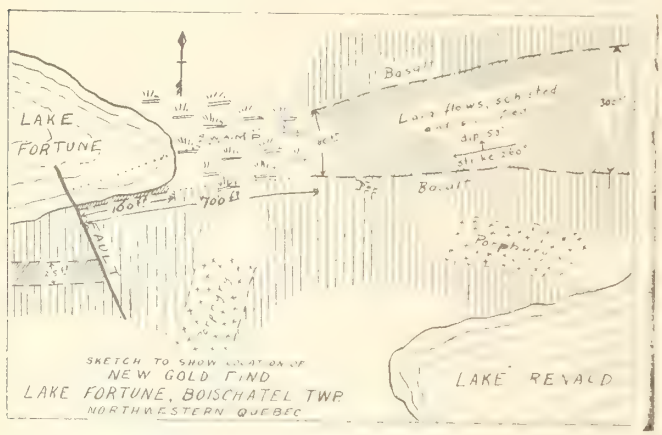
Spectacular Discovery at Lake Fortune

New Find on the Oldest Gold Property of Northwestern Quebec

By ALEXANDER GRAY

The most remarkable gold find of this year has been made recently by Messrs. W. P. Alderson and A. A. MacKay, mining engineers of Montreal. Both the accounts brought out by those that have seen the new find and the specimens of ore indicate that this is a discovery of genuine importance. Messrs. Alderson and MacKay are familiar with the spectacular outcrops of gold veins from Porcupine to the Yukon, and as examining engineers have turned down so many of these that the glamour of a second "golden sidewalk" is not at all likely to confuse their judgment of the vein's ultimate value.

Mr. MacKay made the discovery on the edge of Lake Fortune. An outcrop of mineralized schist on the water's edge attracted his attention as he was prowling about in true prospector fashion. Panning showed gold. The shore was heaped with fallen timber, and it took a day and a half to clear this away. Underneath there was more schist and quartz and more gold. He followed it eastward along the shoe for 160 feet, where it is covered by a swamp. All along it showed free gold, as well as sulphides and tellurides in large amount. At the western end it is terminated by a fault. Seven hundred feet to the



SKETCH TO SHOW LOCATION OF NEW GOLD FIND LAKE FORTUNE, BOISCHATEL TWP. NORTHWESTERN QUEBEC

east of this fault, beyond the swamp, the schisted zone outcrops again, and is 80 feet in width. It is heavily mineralized, pans gold all the way across, and shows visible gold in places. Still further east the schisted area widens to 300 feet. The assay returns from samples brought out corroborate the visible evidence.

This new ore-body is within sixty feet of some of the old workings of years ago. Former owners of the Lake Fortune were unfortunate in that their pits and drifts were misplaced. Now that the property is in the hands of experienced mining men who will apply every dollar of expenditure to advantage and who will find everything on the ground there is to be found, the hopes of the numerous engineers and geologists who have considered well of the Lake Fortune property are more than likely to be justified.

The Lake Fortune property was staked in 1906 by Auguste Renaud and Alphonse Olier. In 1911 the Union Abitibi Mining Company was formed to work it, stock was sold to the public, with a bonus of large promises, some machinery was brought in across the winter road from Larder Lake, and a mill was built. Little mining development was done outside of a 150 foot shaft and some surface pits, and needless to say, the company failed.

The Lake Fotune Mining Company took over the property at this juncture, and made some more mistakes. The Union Abitibi had made only a flying jump at milling. Periodical salvage operations were more in evidence than efforts to attain to gold production. There was just enough gold to entice the respective owners to do those things they should not have done. Professor Bancroft, Mr. Dresser, the Geological Survey, Supt. of Mines Denis, and those who had given the geology adequate thought, never faltered in their belief that Quebec would produce gold mining areas. Undoubtedly the country has been and is inaccessible, but it is no more so than other fields were. The factor of inaccessibiity did not weigh too heavily upon some of the pioneer gold mining organizations in this part of Quebec. They built mills before they had

Saw-mill and Power-house on Lake Fortune

ore. The Lake Fortune Mining Company is an outstanding example of over-optimism. The $400,000 spent (or raised) by its former owners is represented in the almost fully-equipped mill, the excellent sawmill and the modern machinery. What work was done is a sad commentary upon those responsible for it.

This company, of course, suspended operations as well. The property went under the hammer, and was acquired by Messrs. George Bonner, J. H. Goyer and some Montreal colleagues. These did not continue the wasteful policy. They acquired the property and premises at a liquidator's sale, tried to make them attractive to those who know more about the economics of mining than they do themselves, and for five years they have hoped someone

Battery of Tremaine Stamps in Lake Fortune Mill

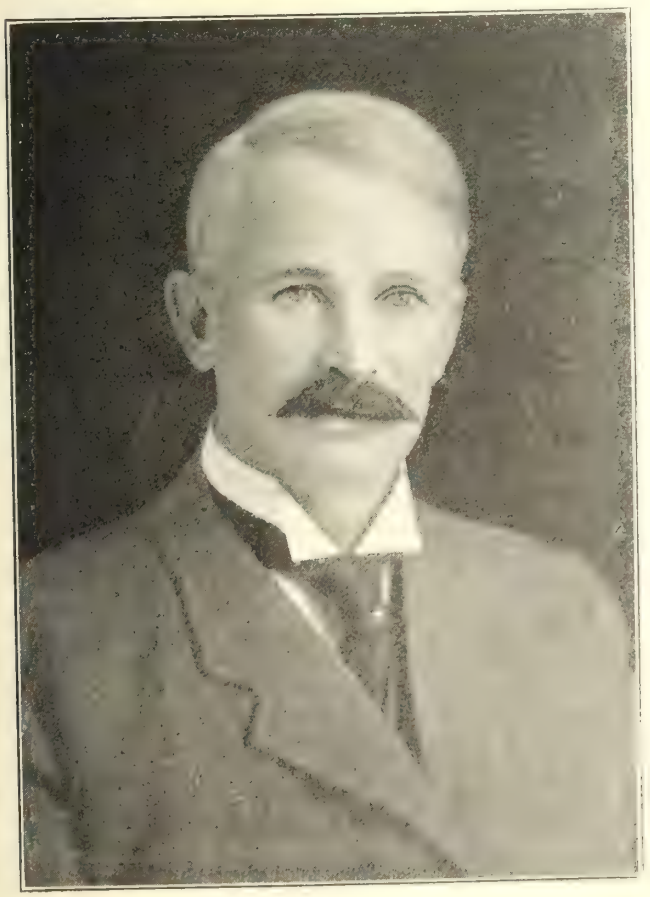
with vision and judgment would come along and do what Mr. Mackay and Mr. Alderson have done. They have a water power right that may be useful. Their mills and machinery require only slight additions to make them useful. Messrs. Alderson and MacKay have given the company the talismanic touch. Messrs. Bonner and Goyer hung on and may be enabled to hand out substantial returns to themselves and the shareholders in general.

Three months ago Messrs. Alderson and MacKay took a working option on a majority of the Lake Fortune shares. They were encouraged to do this by the favourable reports on the property by Mr. Dresser, Dr. H. C. Cooke, and others who had examined it. The terms called for certain expenditures over a three-year period. The first examination was disheartening. In spite of some spectacular showings, the returns from 150 channel samples from the old workings did not warrant the extensive operations at first contemplated. As Messrs. MacKay and Alderson, who were spending their own money, were obviously competent judges and thoroughly in earnest, Messrs. Bonner and Goyer extended the option and revised the terms. Mr. MacKay returned to re-examine the property—and made the find within a week. He has returned to the property to continue the work on what may prove to be the first gold mine in Northwestern Quebec.

R. H. FLAHERTY PASSES

On Wednesday, August 15th, Robert Henry Flaherty died at his home in Port Arthur, Ontario, aged 67 years.

Mr. Flaherty was born in 1856 at the Toltic copper mine in Michigan, where his father was engaged in the designing and construction of shaft-houses for various iron and copper mines throughout the State. He spent his childhood in Houghton, and grew to manhood in Marquette. Entering his father's employ at an early age, he mastered the millwright trade. While engaged later as superintendent with a contracting firm in Minneapolis, he attended night classes in mining engineering at the University of Minnesota.



The Late R. H. Flaherty

Mr. Flaherty's iron mining career began at the Chapin Mine, Iron Mountain, Michigan, and continued from that state into Minnesota when the Mesabi range was opened up. He took the first steam shovels to the Mesabi range in 1892, into what was then an unbroken wilderness.

His first experience in Canada was at the Foley Mine, at Mine Centre, from which he produced $200,000 in gold. Later he put down the Burleigh shaft in the waters of Lake of the Woods, searching for the Sultana vein. Later he returned to Mine Centre, operating the Golden Star Mine until it was closed down in 1899.

In 1900 he was placed in charge of the United States Steel Corporation's operations in Canada, and with a large staff of engineers and prospectors began extensive investigations on the iron ranges of Ontario. A thorough search was conducted at Steep Rock Lake, Atikokan, Mattawin, Kaministiquia, Loon Lake, Nepigon, Onaman, Poplar Lodge, Little Long Lake, and other localities. He continued at this work, with headquarters in Port Arthur, until the Steel Corporation discontinued its efforts in 1910.

In 1910 Mr. Flaherty became consulting mining engineer to Mackenzie, Mann & Co., of the Canadian Northern Railway, in which capacity he was required to travel the mining regions from coast to coast. He remained in this position until they closed their mining department in 1915. Since that time he has been employed as consulting engineer by various interests in the United States and Canada, his headquarters being in Port Arthur.

A widow, one daughter and three sons, Robert J., David and Arthur, survive. "Young Bob" is well known in Canadian mining circles, particularly on account of his explorations in Belcher Islands and the interior of Ungava, which he has deserted for the "movie" world.

Mr. Flaherty's death leaves a sad blank in the minds and hearts of a host of friends in the United States and Canada. His broadly human outlook and his cheerful disposition resulted in deep and lasting friendships. His knowledge of mining affairs, particularly of Canadian iron ores, made him an authority in his professional work. All of us, his friends, regret his passing, and will long hold his memory in esteem.

J. J. O'Connor.

RARE EARTHS MINERALS

These are a group of minerals containing uncommon oxides of an earthy nature; they are found in pegmatite dikes, and in the sand and gravel formed by the weathering of these rocks. In panning for gold, a heavy tail of red, yellow, orange, black, or white mineral should be tested for this group. Zircon, monazite, thorite, gadolinite, allanite or cerium epidote, columbite, and tantalite, are the principal minerals of the group. From them are extracted substances used in the manufacture of gas mantles, electrodes for arc lamps, ferro-cerium for gas lighters, and mesothorium which is similar to radium and used for the same purposes. Columbite and tantalite yield the metal, tantalum, worth $18 an ounce. From monazite and zircon is extracted the metal zirconium, used as a hardener for steel. Zircon concentrate sells for $100 to $400 a ton, and is used largely for making a refractory lining for furnaces.

Welfare Work at Anyox

By F. M. KELLEY*

Anyox is located on the north shore of Granby Bay, on Observatory Inlet, the easterly branch of the Portland Canal. It is five hundred and sixty miles north of Vancouver and a hundred odd miles from Prince Rupert, its nearest neighbor city. It is the industrial as well as the operating centre of the Granby Consolidated Mining, Smelting and Power Company, which is not infrequently referred to as the greatest producer of copper under the British flag. Some twenty-four hundred people at present call Anyox home. Some of them have been here since 1910, when Granby first acquired the Hidden Creek properties, which are the main source of the ore that keeps the smelter operating. The smelter was started in 1910, and has been in continuous operation, with the exception of three short periods, ever since. The mine is located about one mile from the waterfront, where the main portion of Anyox town is situated between the Coke Plant and the Smelter units. Between the Beach section and the Mine section of the community a considerable rivalry has always existed; and while this rivalry does not affect the efficiency apparent on every hand, it is largely responsible for many rattling good games of the kind indulged in by ardent athletes.

The Problem of the Isolated Community

In most centres of this kind, remote from cities and their advantages, the problem of an industrial concern is to make conditions as liveable as possible for its employees. The ordinary procedure is to furnish certain facilities in the shape of ball grounds, dance hall, gymnasium and picture theatre for the relaxation of the men on the job. In most cases each man is assessed monthly a certain sum, which is deducted from his time check, and an official of the Company, connected with the town management or facilities department, invariably acts as a welfare agent. As a rule, where welfare work is attempted at all, the employee has very little to say about what shall be done or to what extent it shall be done. It is not so in Anyox, where a new scheme is being tested, and where its success or failure will depend almost entirely upon the members of the community. Just such an organization as has been built up here it would be impossible to duplicate in other places; and while undoubtedly not altogether perfect as yet, its initial success would seem to indicate already that the effort is in the right direction.

Co-operative Venture at Anyox

The Anyox Community League comprises at present an active membership of five hundred employees of the Granby Company, the appeal of the League's various activities being the only incentive for these members to contribute voluntarily the monthly fee asked. Formerly the membership of the League embraced a number of the men employed at the Mine, and there are still a number in that section who are consistent members; but last fall, on account of the thick mantle of snow lying between the Beach and the Mine during the winter period, the League built at the Mine a community hall, embracing concert, dancing, gymnasium and picture show facilities, and handed it over to a club organized at that time, and now known as the Mine Club.

Before the inception of the community league idea, private interests operated the picture show, pool rooms and dance halls, leasing the premises from the Granby Company. Under the régime of the Community League these activities are operated for the sole benefit of the community and prices are kept as low as possible consistent with the best interests of all concerned. The whole affair as now conducted is in the nature of a co-operative effort, the entire profits derived from the commercial sources being returnable to all in the shape of well-kept tennis courts, a modern library and reading room, children's playgrounds, ball grounds, band support, children's field days, winter parties and other entertainments.

Summer Camp, Gymnasium and Library

A popular effort last summer was the inauguration of a summer camp, twenty miles away at the head of Alice Arm, an unusually beautiful spot. There ten families a week were taken care of for a period of two months. It was the intention to continue this from year to year, and arrangements had been practically completed for the present season; but the owner of the hotel in which the camp was to be established, was caught trading in bootleg liquor and the hotel was closed pending the conclusion of the period of enforced detention that resulted. For next summer it has been suggested that the League build a number of small cottages, and very likely this will be done.

Another effort, equally as popular, was the construction of a gymnasium, 40 by 90 feet, well equipped with all necessary appliances, in co-operation with the Granby Company, who assisted materially with both these efforts as they do in the case of every ambitious proposal put forward by the League.

The library and reading room conducted by the League is in charge of a competent librarian, and has on its shelves many books of reference, a wide range of the classics and plenty of fiction, which is being continually added to; while the reading room has all the Coast papers, and the best Canadian, American and English periodicals. There is also the Granby Technical Library, which covers every phase of mining and the allied branches of engineering, and is available to anyone genuinely interested in the mining and smelting of metals.

Business Administered by Elected Council

A Council administers all the business pertaining to the recreational and social activities of the Camp. It is composed of twelve members, elected by ballot. The active secretaryship of the League entails supervision of all the activities fostered by the organization, including picture shows, billiard and pool rooms and soft drink and tobacco stands. The Secretary of the League is the Welfare Agent of the Granby Company.

The general policy of the League is to make Anyox a better place to live in, and the scheme of co-operation it fosters might well be applied to other small communities throughout the country, as well as to the large industrial concerns. By such a means, at very little cost, the welfare of the people might be attended to. A contented community solving its own social and recreational problems without the aid of advantages offered by a city, is worth striving for. In the case of Anyox this ideal would seem to be well on the way to attainment

The Norwegian nitrate factory at Tyssedal, which was closed in 1921, has been converted to the manufacture of aluminium, and will re-open shortly.

* Secretary, Anyox Community League.

Natural Gas and Petroleum Resources of Western Canada

The Importance of the Gas Fields and Characteristics of the Gas

By NEWTON W. EMMENS

Before taking up the subject of the recovery of gasoline from natural gas, and the processes now in commercial operation for doing this, it might be well first to review briefly what is known at this time of the natural gas resources that by development would be made commercially profitable; and, secondly, to discuss just what natural gas is and in what manner gasoline is contained in it.

If we take the map of Alberta and locate on it the places where natural gas has been shown to exist by the drilling of wells, we find that they are many, are at long distances apart, cover a vast area of country, and, with the exception of the Okotoks, Peace River, Medicine Hat, Bow Island and Viking fields, have not had a sufficient number of wells put down to determine definitely either the extent or the productivity of the reservoirs in each locality. The following are such places:—

Monitor	Tp.	32	R. 4. W of the 4th Meridian.
Czar		40	7
Ponoka		43	25
Fabyan-Wainwright		45	7 & 8
Wetaskiwin		46	24
Camrose		47	20
Birch Lake		50	12
Tofield		50	19
Vegreville		52	14
Victoria		58	17
Morinville		56	25

These "fields" are all within easy reach of railway transportation and if sufficient gas of the right quality can be obtained they would form the basis of profitable enterprises.

Use of Gas Would Aid Search for Oil

It must be remembered that the wells in question were drilled primarily in the search for oil and, there being no immediate market for the gas, as such, no attention has been paid to it, the owners of the wells not realizing that natural gas can be used profitably not only for its gasoline content but for the manufacture of carbon-black, and that they do not have to depend on the domestic consumer or the factory owner in order to turn it to account. It is to be regretted that the development of these fields has not been pushed more vigorously and plants installed to utilize the gas, not only because such a policy would add to the prosperity of the community and turn a present loss into an asset, but because the information gained in the drilling of additional wells would define definitely the sub-structure, would enable the extent of the "pool" to be determined, and might lead to the discovery of oil in paying quantities.

It is a well-established fact that one or two wells neither make nor condemn a prospective field when they are drilled in new and untried territory, the geology of which is not worked out in detail, and where a producing "sand" has been found in the wells, even though the "sand" may not contain a commercial flow at the point where the drill penetrates it. The Kevin Sunburst field of Montana is a good example of this. In this field the first well was drilled about 1912 in Sec. 25, Tp. 34 N, R 3 W., and was carried to a depth of 1,755 feet, passing through the "sands" without getting commercial production. All that was encountered in this well was several small flows of gas in sands of the Colorado shales and a "show" of oil. The second well was drilled in 1922 (some ten years later) in Sec. 16, Tp. 35 N, R 3 W., getting commercial oil production at the top of the Madison limestone, and like the first well got small flows of gas in the sands of the Colorado shales. Since then there have been some 95 producing wells completed, 12 of which are gas wells, in addition to 24 dry holes, and there are 50 wells being drilled, with 33 rigs and new locations.

Geological Maps Defective

The work of the U. S. Geological Survey has been of the greatest assistance to the operators in the Kevin-Sunburst field. It was their investigations that discovered the existence of a structural fold favorable to the accumulation of oil and gas. This was followed up by the detailed work of private geologists, upon whose advice the first producing wells were drilled, so that the success of the Kevin-Sunburst field is directly due to the science of geology.

One of the greatest needs in the development of the natural gas and petroleum resources of our own west, second only to adequate capital, is accurate geological maps, as there is very little known over large areas about the detailed character of the rocks, their distribution or structure, and what information is available is conflicting. One report issued by the Geological Survey of Canada states that a broad anticline traverses east central Alberta, which is shown on the geological maps and is spoken of and shown in cross section by F. G. Clapp in his report to the Mines Branch of the Department of Mines, on "Petroleum and Natural Gas Resources of Canada"; while another report issued by the Geological Survey states that no such anticline exists but that the structure is that of a monocline. Inasmuch as the attitude of the strata has an important bearing on the probable location of oil and gas reservoirs, it is important that geological information be correct. In such a case as that above cited the only thing for the operator to do is to have accurate maps made by his own geologist before doing much drilling, which adds materially to the cost of development, and is almost prohibitive to the smaller companies or to the private operator.

Geological Advice Important

Up to the present by far the most important gas fields developed in east central Alberta are those of Viking and Irma-Fabyan-Wainwright, and of these two only that at Viking has been drilled systematically. It has a record of ten wells, all of which are productive and have "open flows" of from 2,000,000 to 7,000,000 cubic feet each per day. This gas comes from the sandy members at the base of the Colorado or Benton shales near the bottom of the Cretaceous formation. In the Irma-Fabyan-Wainwright field, as stated in a previous article, only three wells have been drilled (two more are being drilled now), which found gas at the same geological horizon as those at Viking and having initial "open flow" productions of from 6,000,000 to 10,000,000 cubic feet per day.

The wells at Ponoka, Wetaskiwin (2), Camrose, Tofield (3), Vegreville (3), Victoria and Morinville, encountered relatively small flows of gas in the Belly

River and Niobrara rocks of the Upper Cretaceous system at a considerably higher geological horizon than that containing the big producing sands of the Viking and Irma-Fabyan-Wainwright fields.

Definite and detailed information as to the yield of gas from the Monitor, Czar and Birch Lake fields is not available, but from their location in respect to the geology and what imperfect knowledge we at present have of the sub-structure, it would appear that they are favorably located and if developed should become important producing fields. However, before any large amount of money is expended in drilling, detailed geological investigations should be made so that the most favorable drilling sites, based on the local structures, may be selected and the unnecessary waste of money avoided. The importance of obtaining advice from a competent geologist or petroleum engineer (the latter must of necessity be an oil and gas geologist) is not confined to the information as to where to drill. It is just as important to know where *not* to drill; and while the geologist may not always select the spot where maximum production may be obtained, he is always sure of places where no oil or gas in commercial quantities can exist and where vast sums of money would be saved if he were more generally consulted and his advice followed before drilling. As examples we have only to recall the money literally thrown away in drilling for oil and gas at such places as Pitt Meadows, the Frazer river delta, on Graham Island and other places within the influence of the Coast Range Batholith, and in parts of the "disturbed belt" of Southwestern Alberta, where the rocks are so intensely folded and faulted that the likelihood of finding oil and gas reservoirs in them is almost nil.

Summary of Alberta Occurrences

Taking into consideration all the information available regarding the geology, sub-structure, and petroleum bearing (both gaseous and liquid) strata in Alberta, we can arrive at the following conclusions:

Gas exists in the shales of the Upper Cretaceous measures above the horizon of the Niobrara sandstone in comparatively small quantities, and such wells are not likely to be commercially successful for either gasoline or carbon-black production.

At the base of the Upper Cretaceous and at the top of the Lower Cretaceous measures, from the Niobrara standstone to the Dakota, there exist "sands" that contain tremendous reservoirs of natural gas and probably oil "pools".

It is probable that the Dakota sands can be reached at less depth in that part of east central Alberta extending from the Alberta-Saskatchewan boundary in the vicinity of latitude 52° N and extending in a northwesterly direction just beyond Vegreville and for an approximate distance of five to ten miles north and south of this line. Detailed geological investigations should, however, be made of the proposed drilling sites before actually commencing work within this area, as local conditions probably will be found to exist having an important bearing on the selection of the most favorable places. In this connection it is interesting to note that the rocks of Cretaceous age contain oil and gas reservoirs in the following States: California, Colorado, Louisiana, Montana, Texas and Wyoming.

Not All Gas is Petroliferous

We now come to the second question namely, What is natural gas?

The Encyclopaedia Britannica states that "natural gas is the name given to inflammable gas occurring in petroliferous formations". This is the popular understanding; but is by no means to be applied to all gas that comes from the ground, because many of these gaseous emanations are not petroliferous at all, but are chiefly composed of nitrogen, carbon dioxide, hydrogen sulphide and methane or marsh gas. As examples we may cite the following:—

Nitrogen — the well at Pitt Meadows in British Columbia yields gas that is 99% nitrogen, and the gas from the well on Pender Island, also in British Columbia, consists almost entirely of that element.

Carbon dioxide — In New Zealand the well at Kotuku yields a gas that contains 57% carbon dioxide, the well at Rotorua 79.9%, and the No. 3 bore at New Plymouth 81.7% of that gas.

Hydrogen Sulphide — The gas from wells in Mexico and some of the Gulf coast fields contains sufficient hydrogen sulphide to make the gas very poisonous.

Methane, or Marsh gas. — This gas is of widespread occurrence and is the chief gaseous constituent of all natural gas of the hydrocarbon series, but does not necessarily indicate the presence of petroleum in the containing rock unless accompanied by condensable petroleum vapors. Methane is the only hydrocarbon contained in the gas from the wells of the Caddo field in Louisiana, at a few places in Oklahoma, from the Murraysville sand of Pennsylvania, from some of the Texas fields in Ontario, in the Medicine Hat field of Alberta and at a few other places.

Methane Often Mistaken for Natural Gas

Not only is methane found in the underlying rocks but it is of common occurrence in marshes, along the shores of lakes and in the islands and deltas formed by streams and rivers. In British Columbia notable examples of this are to be found in the vicinity of Arrowhead, where the Columbia river enters the Arrow lakes, depositing its silt and forming a delta. Here it is common to see streams of gas bubbles rising through the water along the shore line and at some distance out in the river and lake where the water is shallow. This gas is caused by the decomposition of vegetable matter, brought down in the sand and silt by the river, under the water. Similarly the methane can be seen rising around Kamloops lake, in the Fraser river delta and at many other places where there are swamps and where vegetable matter is decomposing.

In most places where marsh gas occurs — that is in swampy places — there is on the surface of the puddles of water a scum or film that shows rainbow colors which the layman is prone to take as being caused by oil, whereas it has absolutely nothing to do with petroleum but is a film of the iron oxide almost always found in unused wells, around bogs and in springs from marshy ground. The iron films are easily recognized because they break apart into irregular figures when stirred with a stick, whereas an oil film will not do this but will spread out along the surface of the water without breaking. The presence of this iridescent iron film and the occurrence of inflammable gas (marsh gas) has been responsible for the waste of much money in the useless drilling of wells for oil and gas in localities where they could not possibly occur and where all geological evidence points to this fact. Methane from the decomposition of vegetal matter in the unconsolidated surface deposits is never as pure as that coming from deep-seated rock strata, but is accompanied by more oxygen, as will be seen from the following analyses:—

	Rock gas	Marsh gas
Methane	[illegible]	[illegible]
Ethane	[illegible]	[illegible]
Carbon dioxide	[illegible]	[illegible]

Carbon monoxide	0.50	0.00	0.0	0.0
Hydrogen	2.18	0.00	61.3	0.0
Nitrogen	3.60	0.00	2.2	1.4
Oxygen	0.35	0.00	5.0	3.5
Sulphuretted hydrogen	0.00	0.51	0.0	0.0

Characteristics of Natural Gas

Petroleum gas, the "natural gas" of commerce, as distinguished from the methane gas from rock strata above referred to, consists of methane, ethane, propane and butane in varying proportions according to the "field" from which the gas comes as well as the individual well in that field. It is rarely that the gas from two wells in the same field from the same sand has exactly the same analysis. In addition to the above-mentioned gases, petroleum gas is often accompanied by vapors of the more easily volatilized portions of the oil associated with the gas or contained in the strata through which the gas passes on its way to the surface. It is these vapors, plus most of the butane and a good part of the propane, that are condensed and recovered in the form of gasoline when the gas is treated appropriately.

Methane, ethane, propane and butane belong to the hydrocarbon series of gases and consist of carbon and hydrogen, with the following characteristics:

Name	Percent Carbon	Percent Hydrogen	B.t.u. per cubic foot	Specific Gravity (air = 1)
Methane	74.97	25.03	1065	0.553
Ethane	79.96	20.04	1861	1.037
Propane	81.80	18.20	2654	1.520
Butane	82.80	17.20	3447	2.004

None of these hydrocarbons are liquid at ordinary pressures and temperatures but both propane and butane can be liquified and will remain liquid to a considerable extent if mixed with naptha or low gravity gasoline.

Gasoline Vapor in Natural Gas

It is well-known fact that when a gas comes in contact with, or bubbles through, a liquid, it takes up and carries along minute particles of that liquid in the form to which we have given the name vapor. The amount of vapor a gas will take up and transport depends upon the temperature of the gas and is quite independent of its nature so long as no chemical action takes place between the gas and the vapor. If this vapor-laden gas comes in contact with some cold object, or if its temperature is reduced, it will deposit the excess vapor in the form of a liquid and the gas will retain only the proportion of vapor it can carry at that particular temperature. We have a good illustration of this when, on a warm, damp day, we bring into the air some object that is cold, such as a jug filled with iced water, immediately becomes covered with water that has been extracted from the surrounding atmosphere by condensation due to the lowering of the temperature of the moisture-laden air in contact with the cold object. Another illustration is warm moisture-laden air blowing in from the sea and coming in contact with the colder air from the land, which causes a general reduction in temperature of the warm air and the precipitation of its moisture in the form of rain.

Reducing the temperature of the air is not the only way of extracting its moisture. The same object can be attained by compressing the air, or it can be passed through some medium, such as calcium chloride or sulphuric acid, that has a great affinity for water.

What is true of air and water vapor is equally true of natural gas and the vapors of the more easily volatile portions of petroleum.

Reduction of Rock-Pressure Gives More Gasoline

Oil or petroleum, like natural gas, is not a liquid of uniform composition but is made up of a number of the hydrocarbons that are liquid at ordinary pressures and temperatures, such as pentane, hexane, heptane, oxane, nonane, etc., each of which has one more carbon atom and one more hydrogen atom than its immediate predecessor in the series, and has a different boiling point. If, then, we bring gas into contact with petroleum, or with rocks that contain petroleum, it will pick up and carry along with it the vapor of that part of the liquid that volatalizes most readily at the temperature and pressure of the gas, until it becomes saturated. As the pressure of the gas on the petroleum is reduced, the boiling points of the component petroleum hydrocarbons are lowered, allowing the lighter members to vaporize more readily. It is due to this fact that as the pressure of the natural gas in the well decreases its gasoline content increases. In one field in West Virginia the gasoline content of the gas increased from 300 gallons per million cubic feet to 900 gallons per million, and in Pennsylvania the gas from a Clarion County field increased from 200 to over 800 gallons per million. Both these increases were directly due to the increased gasoline content of the gas caused by the reduction of pressure and consequent lowering of the vaporization point of the gasoline fractions of the oil in the rock.

The gasoline vapor carried by natural gas depends upon the petroleum content of the "sand" from which it comes, as well as upon the pressure, that derived from wells that also produce oil being very much richer in gasoline than that from wells that yield gas only. This gas is spoken of as being either "wet" or "dry". The "wet" variety may contain from one to as high as twelve gallons of gasoline per thousand cubic feet, while the "dry" variety is what contains less than one gallon per thousand cubic feet, down to as low as one-tenth gallon. The process for recovering the gasoline from natural gas depends upon the richness of the gas and its analysis. A description of the different processes and their operation will be given in the next article.

PETROLEUM PARAGRAPHS

Owing to the overproduction of crude oil in the United States, prices have been reduced from time to time till the producer in many districts is finding it not only impossible to operate at a profit, but difficult to avoid losses. The result of this is that many wells are being shut in and there is a talk of several of the refineries being closed down till the situation improves. As a result of this curtailment policy the production of crude oil in the United States has declined 45,278 barrels for the week ending July 21st. This is the first time since last February that an increase has not been registered.

The following are the prices for crude oil now prevailing:

California	$0.60 to $1.04
Wyoming	0.95 1.70
Gulf-Coast	1.05 1.50
Mid-Continental	1.10 2.20
Central States	1.05 1.88
Eastern Fields	0.75 3.00
Sunburst, Mont.	0.70
Canadian, Petrolia	2.28
Canadian, Oil Springs	2.35

The High Prairie Oil & Gas Co. is drilling a test well along the Peace River, in the Lesser Slave Lake region. The hole is being drilled with standard tools and is down 200 feet. An encouraging geological report has been made on the district and oil is expected to be found at a depth of 3,000 to 3,500 feet.

The Imperial Oil Company's well in the Pouce Coupé district, Sec. 23, Tp. 80, R 13 W of the 6th meridian, northeastern Alberta, has been discontinued at a depth of 2,657 feet without finding commercial production of oil. This well did, however, find a gas sand at a depth of 1,650 feet which gave an initial output of about 10,000,000 cubic feet daily. The well is being left in shape to produce gas.

In the Fabyan-Wainwright district, Alberta, the British Petroleums Ltd., are drilling their No. 2 well in Sec. 36, Tp. 45, R 9 W of 4th meridian, and the Imperial Oil Co. are drilling their No. 2 Grattan in Sec. 14, Tp. 45, R 8 W of the 4th Meridian.

The Northwestern Utilities Co. have finished their No. 10 gas well in the Viking field, central Alberta, and are reported to be bringing in another set of tools to drill and test the southern part of the Viking field for oil.

The Imperial Oil Company's test at Red Coulee in Sec. 5 Tp. 16, R 46 W of 4th meridian showed a production of only one barrel per day from the oil sand at 2,525 feet; consequently a string of 6-inch casing has been run, shutting off all water, and the well is being drilled deeper. It is now down 2,600 feet.

THE "TIN HAT" IN MINES

The trench hat, the "old tin hat" that served in some measure to turn shrapnel hail on the war-swept fields of France, is coming into quite extensive use as a means of head protection against falls of rock and ore in the mines of California, West Virginia, Oklahoma and many other states, according to R. V. Ageton, metal-mining engineer of the United States Bureau of Mines. The hats are being used in shaft sinking and in raising operations and around and in hoisting shafts, states Mr. Ageton. The "trench shoe" and similar heavy shoes are also being utilized by miners to protect their feet.

The Cornish miner of earlier days, who has left his mark in nearly every metal mining camp of the United States, usually protected his head with a hard resined felt hat, on which was stuck a candle, the candle being held in place by a gob of mud. The hat was hot, heavy, and cumbersome, but long years of mining experience had impressed on the Cornishman the wisdom of protecting his head from bits of falling rock. His heavy, cumbersome, cowhide boots, with soles half an inch to an inch thick, undoubtedly prevented many an accident to his feet.

Stiff protective hats are still widely used in some mining districts, but in general the custom of wearing stiff hats is not nearly so common in mines of this country as it should be, probably because a large proportion of the foreign-born miners, as well as many American-born miners, now come to the mines from other occupations, without previous knowledge of mining, and do not appreciate the importance of protecting the head and foot from minor accidents. In recent years, however, the Bureau of Mines has noted a gratifying increase in the use of protective devices for the head by the miners of the country. Many of the soldiers had been miners, and came back with a wholesome respect for the trench helmet and the trench shoe. After being discharged, numbers returned to the mines, and brought with them the trench hat and the thick trench shoes. As one miner in an Oklahoma zinc mine expressed it, "If 'the old tin hat' would stop shrapnel, I reckon it'll stop these small pieces of 'jack.'"

Both miners and operators have been quick to recognize the advantages of these war-time devices for mining use, and at least one mining company was so impressed that it bought a large quantity of trench hats and distributed them to its employees.

ONTARIO'S GOLD PRODUCTION

Statistical returns received by the Ontario Department of Mines from producers of gold in the Province for the six months ending June 20th, 1923, are tabulated below.

For the corresponding period in 1922 the output was 476,338 ounces of gold and 76,405 ounces of silver worth $9,899,193. The decrease was due to an acute shortage of hydro-electric power during the first four months of the year. This situation has been remedied by the completion of additional power plants on the Mattagami and Montreal rivers, while other hydro-electric plants to serve Ontario's gold mines are now under construction on the Quinze and Abitibi rivers. With ample power available, increased milling capacity at both Porcupine and Kirkland Lake and the addition of new producers, it is expected that production of gold in Ontario for the full year 1923 will be considerably in excess of the 1922 output of one million ounces.

GOLD PRODUCTION — FIRST HALF OF 1923

Source	Ore Milled Tons	Bullion Gold Ounces	Bullion Silver Ounces	Total Value $
PORCUPINE				***
Clifton-Porcupine	9,20	[illegible]	37	[illegible]
Dome	166,900	94,744	[illegible]	[illegible]

*** In addition to the values given mines reported receiving for bullion marketed $60,269 by way of exchange premium.

TAR SANDS FOR ROADS AND WALKS

A new demonstration of the practicability of using the tar sands from McMurray, north of Edmonton, for sidewalk and road purposes, is being made at the Edmonton Exhibition. A sidewalk has been laid on the exhibition grounds comprising crushed gravel and the tar sand just as it comes from the ground. It is hoped that such experiments as these will demonstrate the value of the McMurray tar sands in road making. The section of road in Edmonton surfaced with the bituminous sand by S. C. Ells of the Geological Survey some years ago has already proved the value of this material for road building.

MINING AND METALLURGICAL RESEARCH

In his valedictory address as President of the South African Institution of Engineers recently, Mr. J. W. Kirkland made an eloquent plea for more research in mine and mill, which he calls "constructive economy". "I am of the opinion," he said, "that much true economy is attainable as the result of research in connection with gold mining." He gives a list of problems requiring solution, which touch all departments of gold mining and milling.

The Collieries of British Columbia

V — The Nicola-Princeton Field; Coalmont Collieries

BY ROBERT DUNN

The Nicola-Princeton coal field of British Columbia is in the southern interior, between the Fraser River and Okanagan Lake. Dr. G. M. Dawson classified it as a part of the great interior plateau. Of the demonstrated commercial fields of the Province it is the least developed and much more exploration work will have to be done before a clear idea is obtained of its economic possibilities. At present, in point of production, it ranks third in relation to the other two productive areas. In 1922 its total output was 270,890 tons, less than half that of the Crow's Nest, and a very small part of 1,754,656 tons which was the total for the collieries of Vancouver Island.

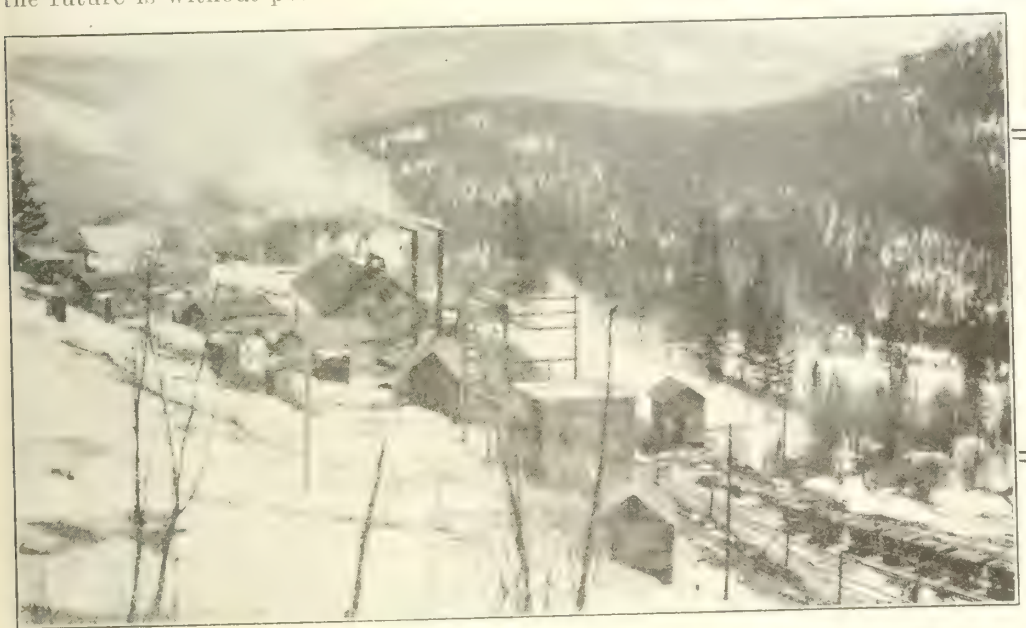
Nicola-Princeton Field of Growing Importance

It would be a mistake, however, to arrive at the hasty conclusion that, because the Nicola-Princeton section has not made marked progress in coal mining, the future is without promise. There is no doubt that there are large reserves of a good quality of coal in this part of the Province. The district has the further advantage of being comparatively close to a rapidly growing and broadening market. It is tapped directly by the Kettle Valley Railway, and Coalmont, for instance, is only some 170 miles east of Vancouver by railway. Probably the lack of a steady demand in the past, owing to the competition of the coals of Vancouver Island, has retarded the advance of mining here; but, as was stated in a previous article, the workings of the Vancouver Island mines are becoming extended, overhead expense for this and other reasons is mounting, it is becoming necessary to open up new parts of the Island field, and as the supply from the Island diminishes and increases in cost of production there can be no doubt that the Nicola-Princeton coals will command more and more attention. Consequently it is clear that the coal resources of the Princeton-Nicola-Kamloops zone are of vital importance to the Province and that their value economically will be recognized in greater degree as the Province grows in population and its industries expand.

Geology of the Coal Basins

Dr. Charles Camsell, Deputy Minister of Mines, Ottawa, when an officer of the Geological Survey, made a detailed geological examination and report on the district. He said that in the valley of the Similkameen River at Princeton, Tertiary coal-bearing rocks occupy a depression in Palaeozoic and possibly Mesozoic strata. This basin contains an important reserve of coal. He described the formation as follows:

"**Oligocene.** — These sedimentary rocks alone in the northern part of the district cover an area of nearly fifty square miles, the basin being fourteen miles long with a variable width of from three to five and a half miles. They consist of thick beds of sandstone with clay, shales and several seams of lignite.



Mine at Blackburn, Coalmont Collieries Ltd.

The base of the series appears to be a very coarse grained sandstone containing many large, rounded, white feldspars in a matrix of calcareous material. This rests on the eastern side of the basin of the Copper Mountain series of rocks, while on nearly all other boundaries the sediments dip under the more recent volcanic rocks which lie as sheets on them. In parts also these volcanics have thrust themselves through the sediments and now appear as islands in the older rocks. The strata do not lie horizontally but have been tilted at low angles, making an irregular series of folds; some faults also occur."

In view of the recent activity at Coalmont Dr. Camsell's observations on the Tulameen measures are of interest. He says:

"The coal basin is almost circular and is occupied by sandstones, shales, clays, and coal-seams. These rest conformably on volcanic rocks consisting of agglomerates, basalts and andesites and are in part covered by more recent volcanic flows. The rocks have

been tilted at low angles and on the outer borders of the basin appear to dip toward the centre. The angles are never more than 45 degrees and are generally less. Small folds appear on Collins gulch and in other places minor faults occur, but on the whole the disturbance is probably not great enough to seriously affect the mining of the coal. The rocks are determined from their fossils to be Oligocene in age and in consequence they are correlated with the coal basins of Princeton, Nicola, Kamloops and with other Tertiary lake basins of the interior of British Columbia."

Of the Nicola and Quilchena the same authority says:

"These two basins of Oligocene rocks occupy depressions in a series of volcanic rocks of Triassic age. The coal is highly altered and the occurrence of small patches of basalt, similar to that covering part of the field at Tulameen, shows that this area also was once covered by a similar outflow. The Nicola basin occupies depressions in two valleys at right angles to each other; a large basin on Ten Mile Creek is connected by a narrow valley with the basin in Nocal Valley; the Quilchena basin lies about eight miles to the east of the Nicola basin. The rocks dip toward the centre of each basin and are broken by minor faults. Superficial deposits mask all the exposures on the lower levels and are very thick in the vicinity of Nicola river."

Six Collieries in Operation

During the last year there were six collieries operating within the area defined, namely, the Princeton Coal & Land Co. Ltd., the Coalmont Collieries Ltd., the Middlesboro Collieries Ltd., The Fleming Coal Company Ltd., the Community Coal & Coke Co., Ltd., and the Chu Chua Coal Co. Ltd. Collectively they employed some 600 ment. Of the group the Coalmont Collieries contributed by far the greater proportion of the field's production, having an output of 142,806 tons. Next in order was the Middlesboro Collieries with 69,330 tons; then the Fleming Coal Co. with 38,485 tons and the Princeton Coal & Land Co., with 19,418 tons. The Chu Chua and Community Coal & Coke Co., followed with inconsiderable amounts.

Coalmont Collieries

Unquestionably the feature of the past year in this field was the showing made by the Coalmont Collieries, which is operating on the southwest side of a mountain on the north fork of Granite Creek at an elevation of 3,600 feet above sea level and 1,600 feet above the Tulameen Valley at Coalmont. The good results are due to the aggressive policy of development inaugurated by the management, composed of W. J. Blake Wilson, president; Gen. J. W. Stewart, vice-president; A. H. Douglas, secretary; D. J. McLeod, treasurer and Donald McLean, manager.

A large amount of exploratory work has been done by several companies and syndicates on this property since 1906. Until 1913, most of this was on the Coalmont side of the mountain, where the edges of the basin were found to be exposed on the "Frazer and Collins Gulch." It consisted chiefly of driving tunnels and boring into the mountain where the coal was found to be of an unusual thickness. It proved to be a high-grade bituminous with good steaming qualities. Unfortunately it is in a much disturbed area, the measures being badly crushed, contorted, folded and broken. Consequently operations were discontinued on this side of the mountain in 1913.

During the same year the Coalmont Collieries Syndicate bonded the property and commenced development at the surface croppings, which were exposed along the side of the mountain on the north side of Granite Creek and 5 miles distant from the town of Coalmont. Here the measures appeared to be comparatively undisturbed. The syndicate continued development until 1916, but owing to the war found it impossible to obtain the necessary capital.

Recent Developments

The property then was taken over by the Coalmont Collieries Ltd., which began development during 1917, following the same policy adopted by the syndicate of developing the measures on the Granite Creek side of the mountain. Motor trucks were employed to transport the coal from the mine to a siding on the railway, and by the end of 1918 the mine had produced and shipped 5,744 tons of coal from the main entries. The seam was shown to be continuous and the coal was uniform in quality.

During 1920 preparations were made for producing coal on a much larger scale by the installation of more plant and equipment. This included an aerial tramway for the transportation of the coal from the mine to the tipple at the foot of the mountain. As a result the Coalmont Collieries may now be considered among the more important of the mining enterprises in the Province. This is demonstrated by the following returns:

	No. of men employed	Output of colliery, tons
1920	36	8,983
1921	80	63,344
1922	143	142,806

The measures at present operated lie in a large basin, with a steep pitch near the surface croppings, which flattens out considerably towards the centre of the basin. All operations to date have been conducted in No. 4 Seam of the series, which is an excellent seam of bituminous coal with an average thickness of from 10 to 14 feet.

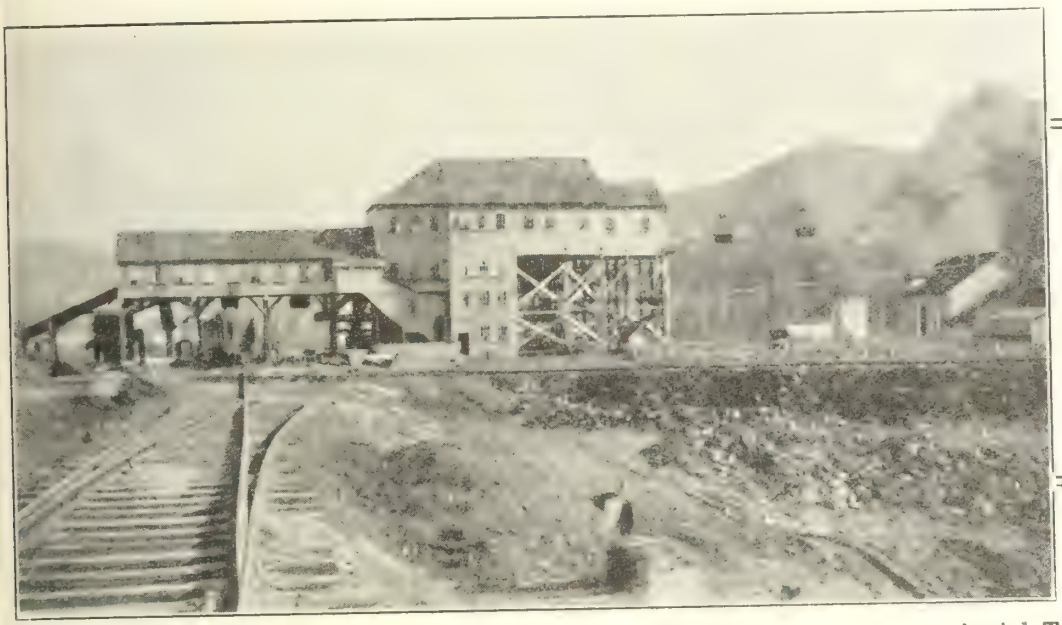
No. 2 Mine

The present mines have been developed by two large and well maintained levels, with the necessary counter levels for ventilation purposes. They are known as the No. 2 and No. 3 mines and are on the same seam of coal but are two entirely distinct operations, being separated by a thick pillar. No. 2 Mine has been developed by a pair of levels following the strike of the seam a distance of 3,250 feet. A large fault or dyke was encountered here and operations were discontinued at the face of this level. Seven sets of headings or chutes were driven from the main level, following the full pitch of the seam to the surface croppings, which are reached at a distance of 700 to 800 feet, the pitch of the measures varying from 20 degrees near the level to 60 degrees near the croppings. An opening then was made to the surface, known as No. 1 level, for facilitating the handling of timber for the working places and for ventilation purposes.

All the workings in this mine are to the raise side of the main level, and owing to the pitch of the seam the mine cars are not taken off No. 2 level. The stall or dump car roads are driven off the headings following the strike of the seam with the necessary crosscuts for ventilation, leaving the pillars about 50 feet square

The roads are 10 feet wide and are generally driven as far as some minor faulting, when the pillars are drawn back towards the main heading, this work being on the retreating system. This commences near the surface and the pillars are drawn towards the No. 2 level.

The coal is loaded at the working faces into small dump cars and is trammed by hand to the main headings, where it is dumped into steel-lined chutes. It runs by gravity to the foot of the chute on the level, is loaded into the mine cars as required and drawn in trips by horse haulage to the top of a surface incline. The cars are lowered over this incline to a siding near the entrance to No. 3 Mine, and there are collected by a 7-ton trolley motor and hauled to the top terminal of the aerial tramway.



Tipple of Coalmont Collieries, showing terminal of aerial tramway from the mines

No. 3 Mine

No. 3 Mine, generally known as the Wilson Tunnel, is the largest and most extensive opening of the Coalmont Collieries and is being used to develop the largest portion of this field. It is at an elevation of 3,600 feet above sea level and is on the same elevation as the top terminal of the overhead tramway. It is an 8 ft. by 12 ft., strongly timbered level with sets up to 24 inches diameter. It had followed the strike of the seam a distance of 3,500 feet when the same fault was encountered as was found in at the face of No. 2 level.

Practically all the work at present done in this mine is in the direction of the dip of the main level. The seam is being developed by three sets of slopes following the full pitch of the seam, which is found to flatten considerable as the slopes are advanced.

No. 1 slope has reached a distance of 1,000 ft., No. 2 about 500 feet, and No. 3 slope, 400 feet. Levels are driven at intervals of 250 feet, from which all the stalls are driven to the raise. The seam has a thickness varying from 8 to 14 feet.

The measures to the dip are under a thick overburden probably 1,100 feet, causing the working places and roadways to be subject to a great deal of "squeeze", for which reason the pillars are left as large as possible. All the working places are driven not more than 10 feet in width and are timbered with heavy framed sets.

The mine cars are collected at the working faces by horses and drawn to landings near the slopes and hoisted to the main No. 3 level by rope haulage. No. 1 slope is provided with a 150 H.P. electric hoist, No. 2 Slope with a 50 H.P. compressed air hoist and No. 3 slope with a 75 H.P. electric hoist. The mine cars are collected on the main No. 3 level by a 7-ton electric trolley motor and hauled in trips to the top terminal of the aerial tramway.

The mines are ventilated by a fan manufactured by the American Blower Company capable of producing 38,000 cubic feet of air a minute against a one-inch water gauge. A Sirocco fan of 100,000 cubic feet capacity is being installed at the entrance to No. 3 counter-level, which will be the permanent airway.

Aerial Tramway

The aerial tramway is 2½ miles in length with a difference in elevation between the upper and lower terminals of 1,600 feet. It is provided with a 1⅛" locked-coil carrying cable on the empty side and a 1⅝" track strand, smooth-coil cable on the full side, and a ⅞" traction cable. It is controlled by a 75 H.P. motor attached by belt and spur gearing to a Fowler grip pulley.

The power house is at Coalmont and is equipped with two water-tube boilers of 28,000 to 30,000 lbs. per hour steaming capacity, fitted with induced draft duplicate pumps and feed-water heating attachments. These boilers have cross-drum and horizontally inclined tubes and are considered the best type of boiler for a steaming plant. At the power house a 600-K.W., 500-volt electric generating plant is installed, with transformers where the voltage is brought up to 10,000 volts and taken over the mountain on high-tension cables to the mine, where it is again reduced to 550 volts for use.

ARSENIC

The United States Geological Survey announces that during the first six months of 1923, nine plants produced refined white arsenic to the amount of 6,035 tons, valued at 8.36 to 15 cents a pound, and 1,183 tons of crude arsenic, valued at 7.46 to 10 cents a pound. One plant at Salt Lake City made calcium arsenate direct from the ore. Imports during the first three months totalled 2,694 tons. Several new plants are planned to operate arsenic deposits in the Western States.

REVISED STATISTICS ON LEAD, ZINC, IRON ORE AND ASBESTOS

The Dominion Bureau of Statistics has issued under date of July 30th, the following finally revised statistics on the mineral production of Canada during 1922.

Lead

The production of lead in Canada during 1922 amounted to 93,307,171 pounds (46653.58 tons) which, at the average market price in Montreal for the year of 6.235 cents per pound was valued at $5,817,702 as against 66,679,592 pounds (33,339.8 tons) valued at $3,828,742 in 1921 when the average price was 5.742 cents per pound. The increase amounted to about 40 p.c. in quantity and 52 p.c. in value.

This production included: (a) 88,606.869 pounds of pig lead produced at Trail, B.C. and Galetta, Ontario; (b) 4,670,621 pounds, the estimated recoveries from lead ores and concentrates exported to the United States, and (c) 29,681 pounds estimated as recovered from ores and concentrates exported from Cobalt to United States smelters.

Production of Lead by Provinces

	Quantity Pounds	Computed Value
British Columbia	87,093,266	85,430,265
Yukon	3,323,508	207,221
Ontario	2,890,397	180,216
Total for Canada	93,307,171	$5,817,702

Shipments of Lead Ores and Concentrates from Canadian Mines in 1922

	Lead Ores	Lead Concentrates	Dry Ores
Tons shipped	17,245	8,823	998
Reported value of shipments	$599,425	754,370	12,388
Metal Contents of Shipments:			
Gold, fine ounces	70	234	8
Silver, fine ounces	1,285,348	611,843	19,922
Lead, pounds	11,245,579	9,363,313	4,264
Zinc, pounds	1,233,901		

Many of the ores of British Columbia contain both lead and zinc. Thus, in addition to the quantities noted in the above table there was 78,350,311 pounds of lead contained in zinc ores so termed because zinc was the predominating metal. Most of such shipments were from the Sullivan mine of the Consolidated Mining and Smelting Company.

Zinc

The production of zinc in the refined state at Trail, B.C. during 1922 accounted for the whole Canadian production and amounted to 56,290,000 lbs. or 28,145 tons which, at the average St. Louis price of 5.716 cents per lb., was valued at $3,217,536. During the year no mine operators reported having shipped zinc ores to the United States.

In 1921, the production was 53,089,356 pounds or 26,544.6 tons valued at $2,471,310 or 4.655 cents per pound on the St. Louis market. The output included 52,988,000 pounds refined zinc produced at Trail and 101,356 pounds, estimated as recovered from ores and concentrates exported.

The increase in 1922 amounted to 6 per cent in quantity and 30 per cent in value.

Shipments of Zinc Ores and Concentrates from Canadian Mines 1922

	Zinc Ores	Zinc Concentrates
Tons shipped	[illegible]	[illegible]
Reported value of shipments	$ 2,075,144	$ 282,570
Metal contents of shipments:		
Gold, fine ounces	19	26
Silver, fine ounces	3,315,505	186,584
Lead, pounds	[illegible]	47,284
Zinc, pounds	[illegible]	4,918,439

The above table is incomplete in respect to zinc in mine shipments since many of the ores in British Columbia contain both lead and zinc, and in the year under review, lead ores, so termed because they contained more lead than zinc, shipped from the mines were reported to contain 1,233,901 pounds of zinc.

Iron Ore

The total shipments of iron ore from Canadian mines during 1922 amounted to 17,971 short tons, the net value of which was reported at $56,993 as compared with 59,509 tons shipped in 1921 with a value of $230,164. This production was the lowest recorded during the past 21 years.

Asbestos

The total quantity of asbestos rock mined during 1922 amounted to 2,562,933 tons. Of this, 2,1[illegible] tons or 84.5 per cent. was milled and 158,023 tons of asbestos was recovered in a merchantable state. The sales for the year amounted to 163,706 tons, for which the producers received $5,552,723 or an average of $33.92 per ton. During the previous year, the average value per ton was $52.89.

The amount of asbestos sold in 1922 was 78 per cent. higher than in 1921, when only 92,761 tons was marketed. During the year, the Quebec Government reduced the royalty from 5 per cent. of the gross value of asbestos shipped to 2½ per cent., as a measure of assistance to the industry. The entire Canadian production was derived from the Eastern Townships of Quebec.

Output, Sales and Stocks of Asbestos in Canada 1922

Classification	Total Output Tons	Sold or Shipped: Total Quantity Tons	Sold or Shipped: Sales value	Sold or Shipped: Average	Quantity in stock, or held at mines at end of year Tons
Crude No. 1	759	[illegible]	[illegible]	[illegible]	1,463
Crude No. 2	2,190	1,351	[illegible]	[illegible]	1,703
Fiberized crude	120	528	[illegible]	[illegible]	[illegible]
Spinning stocks	11,030	6,539	[illegible]	[illegible]	[illegible]
Shingle stocks	18,587	19,647	[illegible]	[illegible]	[illegible]
Mill Board stocks	3,930	1,386	[illegible]	[illegible]	[illegible]
Paper stocks	13,196	14,175	[illegible]	[illegible]	[illegible]
Paper fillers	35,257	15,275	[illegible]	13.07	[illegible]
By-Products (Asbestos sand, finish floats)	12,954	13,412	[illegible]	[illegible]	[illegible]
Total	158,023	163,706	[illegible]	$ 33.92	[illegible]

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

QUEBEC

Along with the good news from the Lake Fortune property at the western end of Quebec's northern gold belt, which receives special notice on another page, comes good news from the eastern end of the belt. The Stabell property, on lot 53, range 8 in Dubuisson township, on the upper reach of the Harricanaw River, has been under option to an influential group of mining men since last spring. These have just completed five thousand feet of diamond-drilling. Specific results of this drilling have not been made public, but the ore disclosed in the cores is understood to be thoroughly satisfactory, with every indication that here is a gold mine in the making. Machinery for sinking a shaft is now on the way to the property. The first scow-load arrived last week, consisting of a boiler, steam hoist and miscellaneous equipment.

Mr. N. C. Stines, representing the American Smelting and Refining Co., has examined recently a number of properties in the neighborhood of the Stabell and at present is sampling the Sullivan property on Lake Demontigny.

The Sisco Island and Dalton group of claims on Lake Demontigny have been optioned to the Quebec Gold Rand Limited, who propose to commence work on the claims immediately. This is the company with which the Duke of Manchester is associated.

The Union Mines Corporation, which holds lot 30, range 8, Dubuisson township, has had a small force of men at work under Mr. J. C. Yancey for some time. Diamond-drilling has showed that a promising ore-body outcropping at the surface continues to a depth of at least 400 feet. It is proposed now to erect a small mill to treat the ore so far disclosed. The property is held by a Chicago syndicate.

On the 17th inst. the Molybdenite Reduction Company, Ltd., shipped a 20-ton car of molybdenite ore from Amos to the Mines Branch of the Department of Mines, Ottawa, for testing purposes. Their property is located in Laconte township on the east side of Lake Malartic.

NORTHERN ONTARIO

Railway Survey to South Lorrain. — The T. & N. O. Ry. Commission has decided to have surveys made of the ground between Cobalt and South Lorrain, with the idea that the Nipissing Central Railway might possibly be extended to that camp. The distance is approximately twenty miles, and it is understood that there are two routes available. While the immediate construction of the line is not contemplated, the commission desires to have the required information in case developments justify its construction.

Kirkland. — The N. O. L. & P. Co. has started the construction of a second power line to the Kirkland Lake district, which will double the amount of power that can be transmitted. The present line has a capacity of 5,000 h.p., and while only 3,800 h.p. is being used, the development of the camp is such that this capacity will probably be taxed in the near future. . The Lake Shore expects to have its 300-ton mill in operation this fall, and the Wright-Hargreaves will probably double the capacity of its mill next year. There is also the probability that the mill of the Tough-Oakes may be started within the next two or three months, and with the work proposed and that now under way, the demand for electric energy will be heavy. Operators in Kirkland have had many complaints to make regarding the quality of the service rendered, claiming that the interruptions were too frequent . The second power line will go a long way toward rectifying this condition. The Power Company is also installing new turbines at its Matabitchoun plant, which will add considerably to its capacity.

Developments on the 10th level of the Teck-Hughes Mine are understood not to be so satisfactory as anticipated. No.1 vein, where cut on this level, while showing satisfactory widths and values, is not as high in grade as it was above, while No. 3 vein, where encountered, showed only low values. It is probable, however, that this is a lean section in the vein, and better ore may be found with a comparatively small amount of drifting. The company has installed a gasoline engine of 125 h.p. in order to insure continuous agitation of the pulp in the mill during the frequent power interruptions that occur. The July output amounted to $80,500. This is somewhat lower than the preceding month, but the mill was closed down for a short time, due to the damage to the ball mill.

On the Sylvanite property, which is owned by interests connected with the Wright-Hargreaves, the main shaft has reached a depth of 725 feet, and will be continued to 850 feet or 1,000 feet. When the shaft is completed, two new levels will be opened up On the 500-foot level approximately 1,500 feet of work has been done, and one ore-shoot about 200 feet long, carrying satisfactory values, has been found.

On the Wright-Hargreaves property adjoining, the underground developments continue satisfactory, and a new ore-body has been found on the 400-foot level The shaft has been completed to 1,000 feet, and a considerable amount of development will be done at this depth. The new rolls for the mill, which will increase the grinding capacity to about 700 tons a day, are to be installed shortly, but it is believed that the main additions to the mill, which will result in doubling its capacity, will be put off until next year.

The Continental is getting its new mining plant installed, and expects to start shaft-sinking shortly. A shaft has been sunk to a depth of about 100 feet by hand, and this will be continued to the 700-foot level. It is the intention to sink another shaft of approximately the same depth on another part of the property.

Gowganda. — The new levels on the Castle Trethewey property, in Gowganda, are showing a satisfactory grade of ore, and the company now has a considerable tonnage of high-grade milling rock developed. It is probable that a small mill will be constructed before long, as this is the only way in which the property can

be worked to advantage. Ore reserves are estimated to be approximately 1,000,000 ounces.

Porcupine. — John Taylor & Sons, of London, have dropped their option on the Scottish-Ontario property in Porcupine. Several diamond-drill holes were put down, but results were not encouraging. It is also understood that on the Imerson property, in Larder Lake, diamond-drilling by the same company did not succeed in picking up the extension of the Crown Reserve vein.

Mining Dividend Record. — During the current year the Northern Ontario gold and silver mines distributed approximately $6,000,000 in dividends, and with the distributions that are to be expected, this total will probably be swelled to $8,500,000 by the end of the year. This will be the largest amount distributed by Northern Ontario mines for the past ten years, but will probably be exceeded in 1924, as the Dome is now paying a larger dividend, and is likely the McIntyre will increase its dividend rate. A new dividend payer is the Keeley Silver Mines, which has already made one distribution this year, and has just declared another of 8 per cent. The total dividends paid by Northern Ontario mines is approximately $130,000,000, of which Cobalt has contributed $96,000,000, Porcupine $32,000,000 and Kirkland Lake $1,500,000.

Unifair Criticism of Mines. — The *Toronto Telegram* has been writing a series of articles on the mining industry of Northern Ontario. The mining interests of this country are always glad to see publicity given to the mines, and while they do not always expect a boost, they do not look for unfair criticism. Some of the statements made by the *Telegram* have not been fair to the individual mines. This probably arises from a lack of knowledge, rather than from a desire to be critical; but it is unfortunate that with a paper like the Toronto *Telegram*, the articles should not be written by a man who has some knowledge of the industry.

NOVA SCOTIA

Injunction Proceedings. — No decision has been reached as yet in the courts at Halifax in the proceedings between the deposed U. M. .W A. officials of District 26 and the provisional executive. It is doubtful whether the injunction taken out by the latter has a legal status, as the U. M. W. A. is not incorporated and has no standing in the eyes of the law. It now appears that the provisional executive blundered when they applied for this injunction, as it is likely to show up their lack of legal status. The fact that the locals have voted in favour of President Lewis' order to return to work is sufficient to show that the provisional executive are in a strong position, irrespective of any injunction proceedings.

Reorganization. — There are fourteen National Officers of the U. M. W. A. in Nova Scotia from Indianapolis, all men of wide experience. Some of them have been employed in re-organizing the union in the strike-ridden state of Kansas, where the notorious Alexander Howatt has been even more successful in keeping that district in a state of turmoil than has J. B. McLachlan in Nova Scotia.

There seems to be no clear idea in the minds either of the public or of the miners as to how the deposed district officers are to be kept out of the U. M. W. A. Locals. This was done in Kansas, and it will be done in Nova Scotia, so that their "bore-from-within" tactics will be prevented in future. The National Officers will remain until this point is settled satisfactorily.

When a U. M. W. .A. reorganization took place in Alberta it was two years before permanent officers were elected. Meantime a new organization was formed and many miners belonged to both. It is not yet certain what the event will be in Nova Scotia.

Record Production Last Week. — In the meantime the coal output is climbing and in less than two weeks after the men returned to work a record output was made. It now appears that all are determined to do their best to try to make up for lost time. There are yet four months of the season before navigation closes and much may be done to overcome the loss occasioned by the strike. With no interruption from boys' strikes (and this is assured by the National Officers, who have notified the locals and the Coal Company that they will summarily deal with these cases, should they arise), the year 1923 may have a largely increased output.

Labor in the mine may, from this out, be better balanced and men may be placed in positions to give the best results from their work, which will be more satisfactory. In the past much opposition has been experienced by the Company on the part of the younger men, who refused to go to the faces to mine coal. The removal of this opposition will greatly assist the community and the coal companies. For years the wages of the classes of labor in which these youths were employed were so high that there was no incentive to strive to enter the skilled classes of mining. Every attempt made by the company was opposed, even to the point of striking. This was most discouraging to the coal companies, who were forced to import skilled labor. It also worked hardship to the miners who had families of boys growing up, because there was no chance of getting their own boys to work until the boy classes moved upwards.

It is now hoped that the number of miners at the working face will be largely increased and the number of detal men decreased. In the United States the ratio of miners to datal men is about two to one. In Nova Scotia this is reversed and the datal men now dominate. This is a large unproductive load to carry and until it is lifted and lightened the coal industry of Nova Scotia will stagger along at a slow pace. It should not be difficult to get the national officers, who have experience in the coal fields of the United States to understand the case, and to see the position in which the coal trade of Nova Scotia is placed. The miners themselves are principally to blame for the anomalous situation, and are suffering from it. When it is rectified Nova Scotia coal mining will assume more nearly the importance warranted by its geographical position and its seams of coal.

Quiet and Efficient Work — Not since the days of the Provincial Workmen's Association has there been such peace, quiet and contentment at the collieries as at present. This is directly due to the recent strict enforcement of the law. The mine officials notice that, as a result, discipline has been restored, orders are obeyed and large coal outputs follow as a result. This rapid increase in outputs has given the public much food for thought. Mutual understanding and joint effort will benefit both mine workers and company, and the false teachings of socialist or communist leaders

will soon be showed up completely. It may be some time, however, before the record of 20,000 tons a day is reached. This will require the opening of new collieries now being made ready.

Indianapolis Officials at Work — The fourteen International officers from Indianapolis have done a fine bit of work. It was a pleasure to see the expert way in which they presented the case of workmen whom the Company had refused to re-employ. They appealed to the management on the grounds that these men were misguided, and that generous treatment would win over to the Company many who still were disaffected. They pleaded the cause of these men very effectively, and they have been re-instated wherever work for them was available.

T. J. Brown at Work — During the colliery strike, T. J. Brown, Deputy Minister of Mines, has kept close watch over conditions in the mines. Though he has a corps of inspectors at work continuously, he inspected each colliery personally, and has made a complete record of conditions at various critical periods. It is thorough work like this that gives the mine operators confidence in the provincial Department of Mines.

Industrial Council for Steel Works — The smoke of battle has cleared away and the opposing forces have met and smoked the pipe of peace on the Sydney Steel Works. The workmen have agreed to run the plant on the co-operative plan proposed by Manager Bischoff, and rejected, some months ago. In future all business affecting the employees and all grievances, real or imaginary, are to be threshed out by a joint committee of workmen and officials. The representatives of the workmen will be selected by secret ballot. There will be one representative to each one hundred men or less, except where the men in the department are too few, when several departments will be grouped and represented by one person. There are about three thousand men employed, and the workmen will have thirty-eight representatives on the general works committee. This committee will appoint five or seven from its own number to meet and act with a like committee of the management in handling all contentious questions. Any workman having a grievance must first take it up with his foreman, and afterwards his superintendent. Failing to get redress, he can then place it in the hands of the department representative, who will have it discussed by the central committee and settled. A case once settled cannot be re-opened except by a seventy-five percent vote of the general works committee. The movement for joint coöperation was brought about by the workmen themselves, who having grown tired of paid agitators, decided that the progress of the steel industry in which they are employed depended upon the united efforts of the employers and employees. It took a long time and caused a considerable loss to the steel workers to arrive at this conclusion, but having once made up their minds and decided that quarreling is poor business they went right ahead, and Sydney may now see better days.

Steel Plant Busy — All departments of the Sydney Steel Works are now in operation. Owing to the cancelling of orders due to the strike the prospects are not as bright as could be desired. The rail mill has only part of a small order to fill, and if new orders are not obtained they cannot long continue to operate. The blooming and billet mill, the rod, nail and wire mills are all busy at present, and it is hoped they may continue so for some time; but those who seem to know the conditions of the steel trade are not over-optimistic. However, the getting together of the men and the company may bring about a condition that and the company may bring about a condition that will enable the company to reach out for a larger share of the steel trade.

ALBERTA

Coal Shipments to Ontario. — That the Canadian National Railway has agreed to accept for shipment to Ontario 4,000 tons of Alberta coal at the rate of $7 per ton net is the latest development in the effort being made by the coal operators of the Province of Alberta, backed by the Provincial Government, to secure a foothold in the market of Eastern Canada for Western Canadian coal. It is made clear by the railway officials that this is not a permanent rate but is merely a concession granted with a view to demonstrating to the consumers of the Province of Ontario the quality of the coal of Alberta. This rate holds good until August 31st, applies only to coal shipped by and consigned to the Alberta Government, and covers a total of not more than 4,000 tons. The collieries of the Province have been given shares of this tonnage to fill and all assert that they could take care of much more at a profit. Howard Stutchbury, trade commissioner for the Province, has left for Ontario to receive and to arrange for the distribution of the coal. The hope in Alberta is that the test will be so successful as to prove the soundness of their contention that, given a reasonable freight rate, they can compete successfully in Ontario with the imported American coals and thus remove for all time the distressing problem of the fuel supply of that section of Canada, a problem that intermittently becomes aggravated through a shortage in the United States and the consequent threatened closing off of that single source of supply.

Not all are so optimistic as this, however, as is shown by the remarks of Prof. E. S. Moore, professor of economic geology, University of Toronto, and director of the Royal Ontario Museum of Geology, who is in British Columbia collecting specimens for the latter institution and who has given the press an interview on this subject. He is quoted as saying that it is only a matter of time before many Ontario industries will be compelled to move their plants either East or West in order to be close to adequate coal supplies. The movement, he thinks, would have commenced before this but for the fact that Ontario, with her comparatively dense population, is a large consumer of manufactured mercandise. Increased population in the West, and the consequent increased demand for industrial fuel both in Canada and the United States, he argues, certainly will lead to the decentralization of industry in favor of the West, where fuel is plentiful.

Prof. Moore states that manufacturers and geologists have been interested in the fuel situation in Ontario for years, that the search for coal has cost much time and money, and that in his opinion there is not in that part of Canada any commercial coal whatever. "There are peat bogs", he points out, "capable of considerable development for domestic fuel and there are lignite deposits on the east side of James Bay with an estimated total of 25,000,000 tons; but neither of these are of much help to industry." Around Port Arthur and in the Sudbury region anthracite substances had been found, but they do not occur in seams or deposits but in veins in a badly broken geo-

logical formation. Tests have proved that they are of little or no use industrially, and some ill-founded hopes have been disappointed.

A permanent cure could not be found by the shipment of Alberta coal to the East, in the opinion of Prof. Moore, for, although such shipments might be of value in emergencies, they could not, owing to high cost of transportation, meet the ordinary, every-day requirements.

New Seams of Semi-Anthracite. — A party of prospectors are reported to have returned to Edmonton, after prospecting the Smoky River coal basin and locating a large area of coal-bearing land . They inspected the area covered by what are known as the Hoppe Leases, which are protected by the Government reserve, and found, it is stated, that the coal formation extends far beyond this reserve. They located coal seams on sections that had not been taken up or reserved. The Hoppe Leases, it will be recalled, were the subject of discussion both in the Canadian House of Commons and the Senate recently. Samples of the coal brought back for analysis show it to be a high-grade semi-anthracite. Three of the seams located by the party are estimated to contain 500 million tons. A railway to the field is projected and survey parties are reported to have been put on the work of reconnaissance.

Strike Threatened — Trouble is threatened in the Edmonton coal district, where the operators have entered into a year's contract with what is known as the District Miners' Federation and the U. M. W. of A. has given notice of a strike. All miners working in the mines on and after the latter date "will no longer be eligible for membership in the U. M. W. of A."

Coal for Ontario.—Premier Ferguson, of Ontario, is reported to be working for a lower freight rate on coal shipped from the Province of Alberta to Ontario. He proposes presenting certain facts and figures to Sir Henry Thornton, President of the Canadian National Railways, which he hopes will result in the fixing of a lower rate than that of $7 a ton, which has been extended to cover trial shipments aggregating 4,000 tons. Ontario's Premier is convinced that tonnage enough could be guaranteed to justify a rate that would permit Alberta's product to compete with Pennsylvania coal.

BRITISH COLUMBIA

Stewart — A controlling interest in the Hercules Mines Ltd., is reported to have been secured by eastern financiers who have arranged for a vigorous continuance of development. The Hercules claims adjoin the "Big Missouri" on the north and are in the centre of the explored mineralized zone of the Portland Canal District. The late General R. G. Edwards Leckie was the president of the Company as well as the managing engineer, but nothing has been done on the property since 1920. Extensive showings of quartz and sulphides were exposed in 1911. The indicated values in gold and silver were encouraging, but a 200-foot tunnel driven in 1920 failed to strike the ore and a shaft sunk on a vein for some 30 feet encountered a fault. It is understood that R. L. Clothier will have charge of the work now planned.

An attractive body of chalcopyrite is reported to have been opened up on the "Morning Star" Group near the head of the north fork of Glacier Creek, Salmon River District. This is close to both the "Sunshine" and the "Ruth & Francis" Groups, which are under bond to the Granby Company and C. A. Mackenzie respectively.

Louis Watkins, of Stewart, made application recently in the Supreme Court of British Columbia for an extension of time in which to survey nine mineral claims adjoining the property of the Premier Gold Mining Co., Portland Canal District. In the course of the argument Mr. Justice Gregory is reported to have observed, "this looks to me like claim jumping." A Supreme Court action is pending between Watkins and the Premier Extension Gold Mining Co., the latter having been incorporated last January with an authorized capital of four million dollars. Watkins, in his attempt to establish title to the Company's claims, is attacking the staking, asserting that the Company and its predecessors have not complied with the terms of the Mineral Act which require the finding of mineral in place before staking, and it is alleged that stakes were planted in the snow and not in the ground.

Prince Rupert — Dr. G. A. Young, of the Canadian Geological Survey, called at Prince Rupert recently after spending some weeks examining the iron ore deposits of the Queen Charlotte Islands on behalf of the British Columbia and Dominion Departments of Mines. On completion of his work in this section he will turn his attention to some of the magnetite deposits of Vancouver Island.

Smithers — The Duthie Mine on Hudson Bay Mountain near the town of Smithers, has been acquired by the Federal Mining & Smelting Co., a subsidiary of the American Smelting & Refining Co. This property has been known as the Henderson Group and for years was the subject of intermittent development without decided results. Within the last year or two J. F. Duthie, of Seattle, became interested and under his direction the work of opening it up proceeded actively. During recent months several cars of ore have been shipped to the Trail smelter from which most encouraging returns were received. This success has occasioned marked mining activity in the district. Several other properties in the vicinity are being developed and a new impetus has been given to prospecting. The Duthie Mine is practically on the line of the Grand Trunk Pacific Ry. It is some 100 miles east of Prince Rupert and some 350 miles southeast of the Premier Mine and is likewise on the eastern side of the Coast Batholith.

H. A. Guess, vice-president and managing director of mines for the American Smelting & Refining Co., who has been visiting British Columbia, authorized the foregoing statement at Prince Rupert. He had just returned from an inspection of the Dome Mountain Property recently taken over by his Company. This also is in the vicinity of Smithers.

It is stated also on the authority of Mr. Guess that these properties will be developed vigorously, that ore will be shipped to the Selby Smelter, California, being transported by team and tractor from the mine to the railway at Smithers, and that Charles Wethered, formerly of Wallace, Idaho, will be in charge.

It is stated that Mr. Duthie will receive $250,000 for his properties, in which he retains a substantial interest.

The Copper Rod Bounty — J. G. Parmelee, O.B.E., assistant deputy minister of Trade and Commerce, Ottawa, is in British Columbia obtaining information upon which to base regulations governing the applica-

tion of the bounty on copper bars and rods which was provided for at the last Session of the Dominion Parliament. This authorizes the payment of 1½ cents a pound on Canadian-made copper bars or rods until June 1924. After that the bounty is 1¼ cents a pound and is reduced each year until June, 1927, when it becomes ½ cent. In June 1928 it expires. At present the only company in a position to take advantage of the bounty is the Consolidated Mining and Smelting Co. whose plant is at Trail.

Greenwood — The uncovering of a new lead of high-grade ore in the Combination Mine of the Eholt Mining Co. has put new life into the mining town of Greenwood. The discovery was made some 230 feet from the portal and good values in grey copper and silver are reported to be established. Drills are to be put to work immediately to further prove the ore-body and a shipment to the Trail Smelter is planned as soon as the ore can be assembled. The Combination is one of the oldest mines of the Greenwood District, having been located in April, 1892.

Old Granby Smelter Being Removed — The Hecla Mining Co., has taken over the old smelter plant of the Granby Consolidated Mining and Smelting Co., at Grand Forks, and the work of dismantling has commenced. The material is to be shipped to Burke, Idaho, for use in the construction of a new concentrating plant.

Fluorite Shipment—Shipment of about 2,500 tons of "reject fluorspar" of the Rock Candy mine, Lynch Creek, to the Trail Smelter will be started shortly. Because of the American tariff against fluorite concentrate, it is not expected that the Rock Candy mine will resume operations, as its product was marketed to a large extent in the United States.

Usk. — John Willman, manager of the Kleanza Company, states that the opening up of the Valhalla Group situated on Kleanza Mountain near the town of Usk, northern British Columbia, has disclosed three veins, on one of which a tunnel was driven 35 feet last year, the sampling of which gave returns between $7.50 and $87 a ton in value. This year they have been drifting on the same vein 1,800 feet lower down. This now is in about 27 feet and, although no assays have been secured, free gold is said to have been disclosed from the portal to the face.

The Trona Mineral Group, composed of three claims on Kleanza Creek, a branch of the Skeena River, also is showing up well with development.

Smithers. — The Provincial Government is extending substantial aid in the construction of roads to assist in the opening up of the Duthie properties near Smithers. The exceptional results obtained from shipments made to Trail from this section have led to much mining activity in the district. The Cascade Group is the latest prospect to attract attention. High-grade ore is reported to have been struck here and a number of mining engineers have visited the property on behalf of eastern mining interests.

Rock Creek. — Frederic Keffer, consulting engineer, and Andrew Jackson, secretary of the Jack Paul Mining Co., of Spokane Wn., recently inspected the Company's property, the Riverside Mine, near Rock Creek, Boundary District, and are reported to be well satisfied with the results of development. They are confident that their operations will lead to the blocking out of a large body of silver-gold-lead ore. The showings already are good and the promotors believe that the Riverside is destined to become an important producer.

Granby Operations. — H. S. Munroe, general manager of the Granby Consolidated Mining & Smelting Co., has announced that the Copper Mountain mine and the Allenby concentrator will be in operation and on a productive basis sometime between September 15 and October 1. The railway spur from Allenby to the mine is being cleared of several heavy landslides and other repairs effected along the line, at the mine and at the mill. There is plenty of ore broken at the mine to keep the railway and the mill at work for the present. Before this is exhausted newly mined ore will be delivered and the permanence of the industry would appear to be assured so long as the market holds. Regarding conditions at Anyox, Mr. Munroe stated that the repairs necessitated by the destruction of the powder magazine by fire, and the damage it caused to other parts of the plant, already were well under way and that the mine and plant at this point were working at full blast.

Final payment on the Wellington mine, Retallack, was authorized recently at a meeting of the Slocan Consolidated Silver Mines Ltd. held at Nelson. Approximately $20,000 has been spent on the purchase and the development of the Wellington since its acquirement by the present holders, practically all this amount being contributed by the directors and officers of the Company. George H. Wiegand, manager, has recommended more development, and a further amount is to be subscribed to carry out this work. It is intended to complete a raise from the main tunnel level to make connection with the old upper workings, to stope out a fine body of clean galena ore opened last spring by a crosscut and drift on the 200-foot level, to explore two stringers recently found in the main tunnel level containing high-grade ore, and to sink winzes on two ore-shoots.

Kaslo. — Col. Henry H. Armstead, mining engineer, has taken up his residence at Kaslo. He is actively interested in several mining properties in that locality. He states that his intention is to make a thorough survey of the Utica mine to determine what course to pursue in its further development.

Telkwa. — A coal seam on Goat Creek, a branch of the Telkwa River, northern British Columbia, is being developed by Messrs Gillespie & Wilson, who plan to have their mine and plant in shape to supply the Prince Rupert and adjacent markets next winter. .

New Colliery Projected. — Diamond drilling continues on the coal lands of the White Lake Coal Land near Penticton, which is within what is broadly termed the Nicola-Princeton field. Fourteen seams are reported to have been found, the largest with a width 20 feet, others running 14, 11, and 9 feet, as w several 3 feet.. The coal is said to be especially goo for steaming purposes and as a blacksmith coal to be as good as that of Pensylvania or Maryland. The Kettle Valley Railway has agreed to take the coal as soon as production starts

July Coal Production — Figures just issued show the coal production of British Columbia for the month of July to be better than for June by about 26,649 tons the total being 212,809 tons. This is due chiefly to the

whose output has advanced from 22,254 to 45,905 tons, an increase of 23,651 tons, or more than double. The explanation is better demand and, as the market for this coal, particularly at this time of the year, is industry, in the form of railways, smelters, etc., the improvement is both significant and gratifying.

In the main the other active collieries of the Province have about held their own. On Vancouver Island the Canadian Collieries (D) Ltd., with 52,531 tons, mined 4,442 tons more in July than in June; but the Western Fuel Corporation, with 51,334 tons, dropped some 846 tons. The Granby Collieries, Cassidy, also had a shorter output by some 912 tons, their total being 18,-714 tons; while Messrs. King and Foster, operating the new mine in the vicinity of Nanaimo, show an advance of about 100 tons. In the Nicola-Princeton field the Coalmont Collieries, with 10,204 tons, produced in July 595 tons more than in the previous month, while the Middlesboro Collieries and the Princeton Colliery dropped slightly, producing 5,737 tons and 780 tons respectively.

The Late Mr. Savage — J. M. Savage, General Manager of the Canadian Collieries (D) Ltd., died on August 12th last while on an automobile tour of British Columbia and Washington State. According to telegraphic advices he collapsed near Wilson Creek, some twenty-five miles out of Spokane. The news is a shock to all engaged in the coal mining business in the Northwest, among whom Mr. Savage was well-known and highly respected. He has been prominently associated with the business life of the Canadian West for many years. Coming to this Province from Winnipeg about the year 1907, he and John Arbuthnot became associated in the organization of the Red Fir Lumber Co. of Nanaimo. A year or so later they launched the South Wellington Coal Mines which later became the Pacific Coast Coal Mines. From this enterprise Mr. Savage withdrew about the time of the initiation of litigation in which the affairs of that concern have since been involved. It was about the year 1916 that Mr. Savage became General Manager of the Canadian Collieries (D) Ltd. While he was in charge, the finances of that Company were completely re-organized. Since then the Company has been following a progressive policy, the exploration, prospecting, and development of its extensive coal lines on Vancouver Island proceeding hand in hand with economic production.

The Mineral Province of Western Canada

Has produced Minerals valued as follows Placer Gold, $76,542,203; Lode Gold, $109,647,661; Silver, $59,814,266; Lead, $51,810,891; Copper, $170,723,242; Zinc, $24,625,839; Coal and Coke, $238,289,565; Building Stone, Brick Cement, etc., $36,605,942; Miscellaneous Minerals, $1,358,839; Making its mineral production to the end of 1922 show an

Aggregate Value of $734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive $94,547,241; for five years, 1896-1900, $57,605,967; for five years, 1901-1905, $96,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for 5 years 1915-1920, $189,922,725; 1921, $28,066,641; for the year 1922, $35,158,843.

Production During last ten years, $339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

VICTORIA, British Columbia.
THE HON. THE MINISTER OF MINES.

PROVINCE OF QUEBEC

MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

MINER'S CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONORABLE J. E. PERRAULT,

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

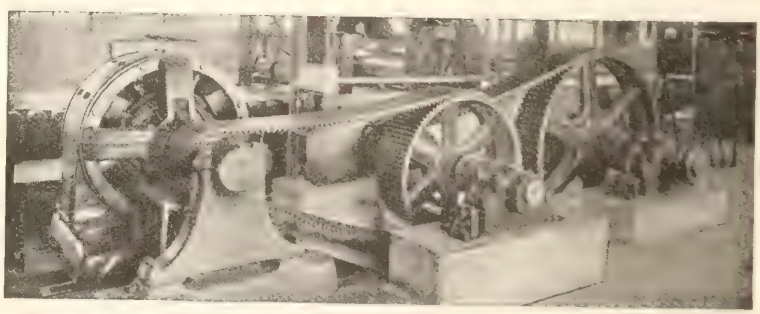
MORSE CHAINS

THE MORSE "ROCKER JOINT"



A few of the Morse chains in use at the Raymond Lead plant

Using chain drives speeds up production, cuts belt expense and overtime wages and operates with practically no repairs.

Write for Booklet

CANADIAN AGENTS

Jones & Glassco, Regd.

MONTREAL, TORONTO.

O. W. Ludwig, *Plant Superintendent of the Raymond Lead Co., Chicago, says:*

"Thirteen years of service without a repair is our experience with two 100 H.P and ten 20 H.P. Morse Silent Chain Drives.

"When we moved into our present plant thirteen years ago, we installed the present Morse equipment of silent chains for our two lead mills and ten hydraulic pumps. We had always previously used leather belts, but not without considerable trouble. For instance, if the operator was not careful — and gave the motors too great a load, the leather belt would slip and in some cases burn out. While with the Morse Chain Drive we overload them at times up to 15 H.P. without the slightest trouble.

"When we used leather belts on the hydraulic pumps, if a pump packing suddenly gave way, the water would squirt all over the pump as well as adjoining pumps, causing the leather belts to get wet. This often necessitated a shut-down on 3 to 4 pumps to dry out each belt, thus causing a loss of time by the men, which resulted many times in paying overtime to catch up on the work. Of course, with our Morse Chain Drive we have no such trouble—this positive drive prevents slippage and is not affected by water.

"Leather belts lasted us 2 to 3 years at the most, while our Morse Chain Drives have already lasted 3 to 4 times that long and seem good for many more years. So Morse Drives have cut our expense materially, speeded up production, cut out overtime wages and saved floor space, for they operate on shorter centers."

IF YOU WANT SECURITY

AND SATISFACTION

USE

"HARRIS"

HEAVY PRESSURE

for Heavy Line Shafting and all ordinary Service

IMPERIAL GENUINE

where exceptional strain or shock is encountered.

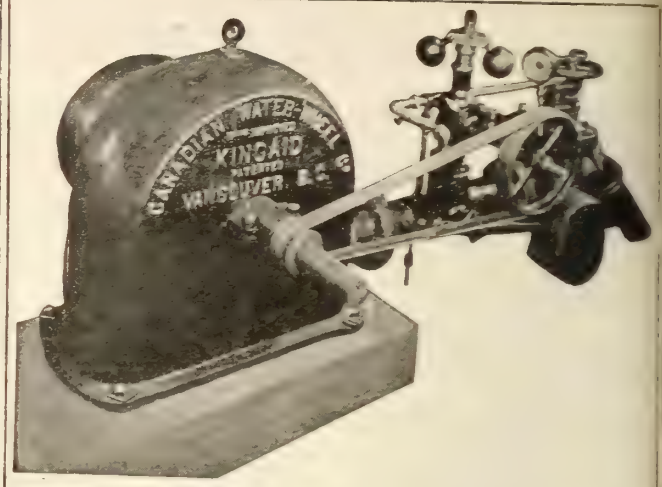
For Heavy Duty Engines Stationary or Marine

No Better Babbitt Made

Contains No Lead

The Canada Metal Co., Limited

Hamilton Montreal **TORONTO** Vancouver Winnipeg



MAKE YOUR **Idle Water Power Pay Dividends**

IMPROVED KINCAID WATER WHEELS DEVELOP ECONOMICAL and EFFICIENT POWER FOR MINES

The "KINCAID" water-wheels deliver the full theoretical power calculated from a given quantity of water from a stated head.

Using the best materials combined with careful workmanship results in the "KINCAID" being a water-wheel as near mechanical perfection as it is possible to make it. Let us demonstrate its possibilities to you.

Agents for PETERSON FLOTATION CELL

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index may be found upon reference to their advertisements. An alphabetical index to advertisers will be found at the page facing the inside back cover. The following regulations apply to all advertisers: — One-eighth page, every issue three headings; one-quarter page, every issue six headings; one-half page, every issue, twelve headings, full page, every issue, twenty-four headings. Buyers who are unable to find in the classification here given such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can, in all probability, refer them to proper sources.

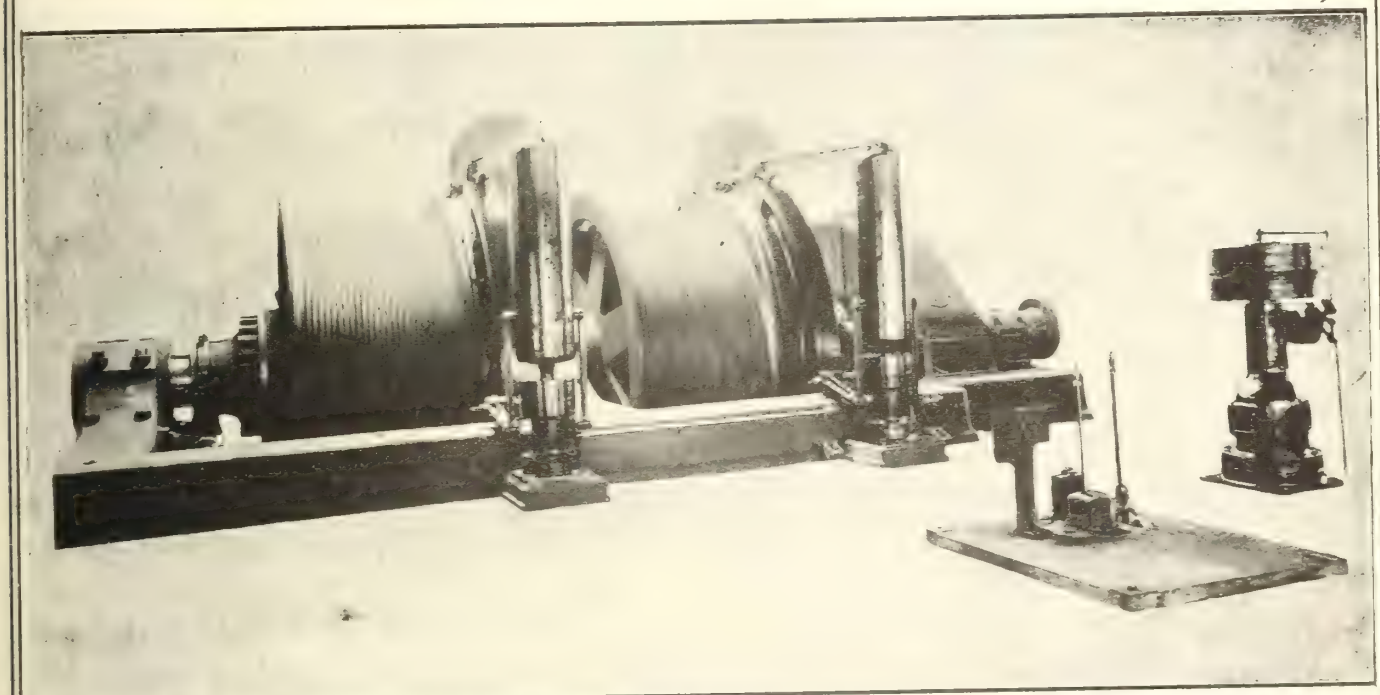
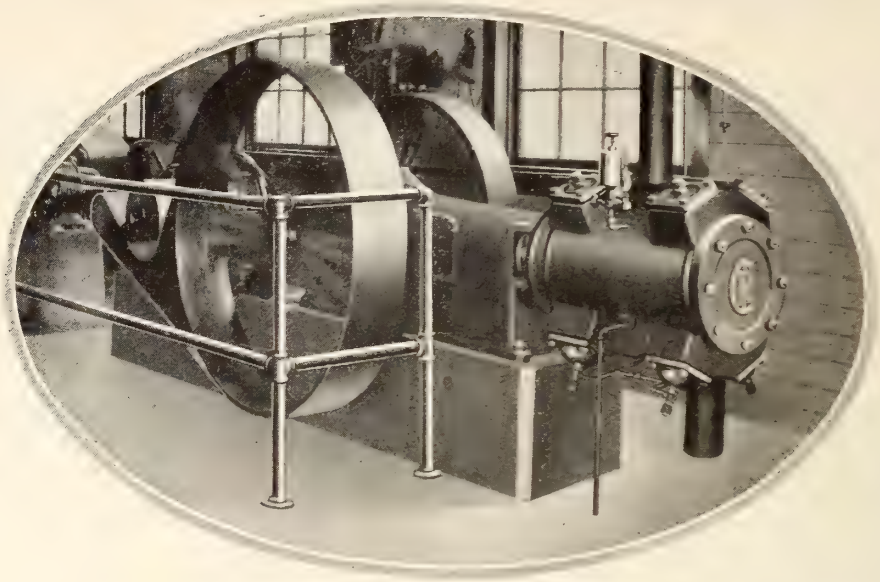
"Ottumwa" Hoists
Built in Canada



This Hoist hauls a 15 Ton Load on a 45° Slope at 1600 ft. per minute. Drums 107" Dia. by 50" face. 1¾" Rope. Driven by 900 H.P. Motor Through Single Reduction Herringbone Gears. Clutches and Brakes Oil Operated.

One of several exclusive features of the "OTTUMWA" Hoist is the PROPORTIONAL PRESSURE CONTROL for power operated brakes. Successive positions of the hand levers give definite and increasing increments of braking effect. A simple and reliable device which effectively replaces the usual complicated gear with superior results. Has proved its worth on many installations.

CANADIAN VICKERS, LIMITED
MONTREAL, QUE.



For The Small Mine or Quarry

"Ingersoll-Rand" Compressors and Drills

THE small compressor for furnishing air to three or four rock drills, a small hoist or pump, should be as efficient, reliable and as nearly automatic in action as modern design and skilled workmanship can make it.

Efficient because the lower the cost of compressing air, the greater the saving at the time when funds are most badly needed and hardest to get.

Reliable because the property is often miles from a railroad; there is usually only one compressor and if it breaks down work will be held up until repairs can be completed.

Automatic because the services of a skilled engineer are seldom available and the operator's time can often be used to better advantage in other ways.

For the small mine or quarry there is no simpler or better combination than an "Ingersoll-Rand" Class ER or FR Compressor and Ingersoll-Rand "Jackhamers" or Convertible Drifters and Sinkers.

Furthermore, you can always satisfy yourself before buying as it is easy to locate nearby installations where the worth of this combination is being constantly proven. Class ER and FR Compressors are straight-line, single-stage, double-acting units fitted with Ingersoll-Rand Plate Valves. They are simple, sturdy, compact in construction, reliable, automatic and economical in operation. Class E R units are furnished for long or short belt drive; Class FR for steam drive.

Write our nearest branch for bulletins and names of users in your locality or outline conditions and we will recommend a complete plant to meet them.

All Shoulders To The Wheel!

So much interest and close co-operation has already been evidenced that the success of

AMERICA'S MOST IMPORTANT INDUSTRIAL EXPOSITION

is assured, and there is every indication that this year's Exposition will be the greatest of its kind in the country, if not in the world.

9th NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES

GRAND CENTRAL PALACE, NEW YORK

SEPTEMBER 17th-22nd

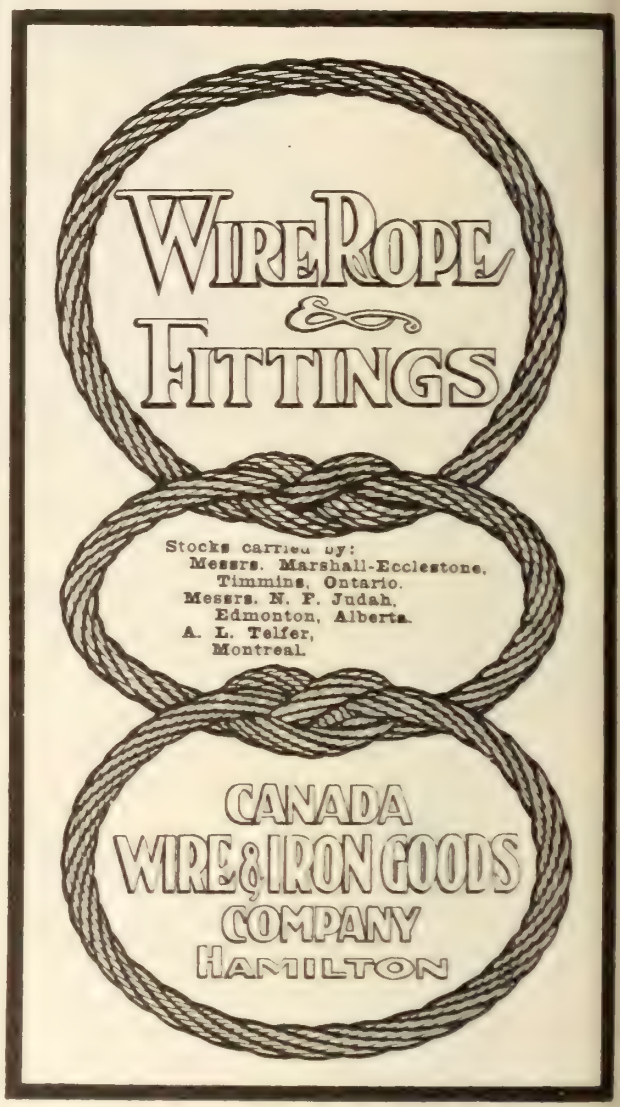
(The Only Chemical Exposition To Be Held This Year)

Everyone who knows what a tremendous factor chemical knowledge is to every industry "owes some of his time" to directing the attention of executives to the great benefits to be anticipated by a visit to this Exposition. There is no industry in the country that cannot be helped by the ideas to be given at this Exposition.

One of the important features will be the presentation of ways and means to enhance labor productivity. The utilization of waste products will also be given special attention.

Exhibitors are making elaborate plans to have this year's exhibit surpass any showing made during previous years.

For further information address National Exposition of Chemical Industries, Grand Central Palace, New York



The contributing factors in making good Wire Rope are:

Men who know how
The best grade of materials
The most Modern Machinery

We have all 3 and are producing the goods. Give us a trial.

Our Wire Rope Catalogue is an invaluable reference book and contains many helpful ideas on the care of wire ropes and cables as well as information on the best kind of rope to use on all classes of work. A copy sent upon request.

Our other lines of Manufacture are Wire Cloth for all uses, Perforated Metals, Wire Pulp Mats, Clothes Lockers, Machinery and Window Guards, Pulp Mats, inquiries solicited.

Graphite, by H. S. Spence.

Gas Producer Trials with Alberta Coals, by J. Blizard and E. S. Malloch.

The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the developing of the general mining industry of Canada:—

Fuel Testing Laboratory.—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.

Ore-Dressing Laboratory.—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.

Chemical Laboratory — Analyzing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.

Ceramic Laboratory.—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.

Structural Materials Laboratory.—Experimental work on sands, cements and limes is also undertaken.

Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to The Director, Mines Branch, Department of Mines, Ottawa.

Applicants for publications not listed above should mention the precise area concerning which information is desired.

Summary Report — The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist's report is required, or what subject they are interested in.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

Communications should be addressed to The Director, Geological Survey, Ottawa.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387

Dividends.

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Publications

For list of publications, illustrated reports, geological maps and mining laws, apply to

Thos. W. Gibson,
Deputy Minister of Mines,
TORONTO, CANADA

FOR YOUR CONVENIENCE IN DEALING WITH MATTERS ELECTRICAL

A Canadian manual of current information concerning matters electrical in the Dominion will be published a few weeks hence under the title of

THE ELECTRICAL DIRECTORY OF CANADA

Where To Buy Anything Electrical — a Buyers' Guide of 350 pages, listing 1,200 classified electrical items, covering almost every item of electrical apparatus, appliance or supplies in current use.

The Electric Power In Each Locality of the Dominion — The current voltage company or commission for 1,050 localities. This comprises almost every locality in the Dominion, having a population of 300 or upwards.

The Principal Officers, Capitalization and major plant equipment for each company producing electric power. Edited specifically for Canadians from the Canadian view point.

The Product Of Many Months Of Intensive Effort by a qualified staff under technical direction.

Information obtained From Original Sources—through an extensive correspondence with responsible officials in all quarters of the electrical industry.

Serving Canada's Mining Industry

It is many years since The Imperial Bank of Canada, recognizing the importance of the Canadian Mining Industry and realizing the need of banking facilities for those engaged in its development, first opened a branch in Northern Ontario.

Since then the Imperial Bank's service has gradually extended until the mining interests in the rich area between North Bay and Hearst are now linked up by a complete chain of 12 branches.

This Bank's service to the mining industry is not confined to Northern Ontario alone. In all the mining areas throughout Canada the "Imperial" is rendering a valuable and complete financial service.

IMPERIAL BANK OF CANADA

For Economy Use Hercules Flotation Oil

The proof of the value of a flotation oil lies not in the cost per gallon, but in the amount of concentrate recovered by its use.

Pine oil is the best frother known, and Hercules Pine Oils have the advantage of complying strictly with specifications and being uniform in every shipment.

We ask you to compare the price and value of Hercules Pine Oil with others on the basis of net cost per ton of ore treated.

We should welcome an opportunity to demonstrate to you the economy which results from the use of Hercules Steam-distilled Pine Oil.

:-: EDITORIAL :-:

A JOB FOR THE INSTITUTE

Last week we suggested that the Canadian Institute of Mining and Metallurgy should, for its own sake as well as for the benefit of our mining industry, undertake to apply itself to the solution of problems of national scope and importance. Its success last spring in stimulating active interest from coast to coast in the fuel problem demonstrates its capacity for such work. The effort should be carried on not sporadically but continuously. Today we shall suggest specifically a problem that may warrant the Institute's attention.

On another page Mr. H. G. Nichols discusses the problem of depletion allowance in respect of mine taxation. Taxation affects vitally every operating mine in Canada, and the depletion allowance affects particularly metal mines. Thus, although the taxation is in the hands of the provinces, with the exception of the prairie provinces, whose mineral lands are still administered by the federal government, the question is of national scope and importance. It is highly desirable that the mineral tax regulations of the provinces and the Dominion should be reasonably uniform. It is also most important that no part of the mining industry in any part of the country should be subject to unjust discrimination. The problem would thus appear to fall within the scope of Institute activities.

In those provinces where there is an important mining industry, associations have been formed to represent the mine owners before the public and before the various governing bodies. It is a phase of the activities of the Mining Association of British Columbia that Mr. Nichols discusses in his article. The Alberta colliery owners have been very active recently in a combined attempt to extend their markets. The Ontario Mining Association has become an influential body during its comparatively short existence. The Quebec asbestos operators are suffering sadly from the lack of concerted effort such as is secured through such an association. The mining industry of Nova Scotia is mainly in the hands of one company, and consequently its negotiations with public authorities are a comparatively simple matter. But there is no national representative of the Canadian mining industry except the Institute.

Unless the Institute tackles these problems of national scope, no one will. Of course there is the possibility that a new organization will be formed to study and solve such questions and to see that the solution is put into effect; but we cannot see that any new organization is necessary. Those primarily interested are to be found already, almost to a man, within the Institute's membership. If any remain outside, it is because membership is not sufficiently attractive to them, and constructive effort on an adequate scale is more than likely to provide the missing attraction.

We have made a specific suggestion. It may not be a good one; let someone make a better. But for heaven's sake, let us start something going.

A PROMISING HALF-YEAR

Canada's mineral production for 1923 is likely to approach, if not to surpass, the record year, 1920. This is indicated by the report from Ottawa on the output of the first six months, which is noticed on another page. The half-year's output is valued at over $87,000,000, an increase of 44 per cent. over that for the first half of 1922. This is in spite of curtailment in the production of gold due to the serious power shortage in Ontario. The revival of industry in general throughout the country is the most important factor contributing to this sudden increase. But, more important in the long run, the Dominion's capacity to produce minerals is being expanded steadily, thus aiding to swell the total by a moderate but progressive annual amount.

The most outstanding advance of the year is, of course, in the nickel industry, which has reached its pre-war dimension and promises soon to exceed it. Intensive research and judicious advertising are jointly responsible for this satisfactory condition. With the aid of South Lorrain, the Premier, and the Mayo camp, silver is holding its own. With Anyox going at full blast, the new Britannia mill in operation, Copper Mountain about to join the list of producers and Rossland on the point of operation, the outlook for copper production is bright. Before the year is out the new mill at Kimberley for Sullivan ore will make the figures for lead and zinc climb.

The asbestos district has "come back" wonderfully during the year, thus far, and no diminution of sales is foreshadowed for the second six months. The coal miners of Nova Scotia are making up rapidly for the ground lost during the strike, and there is still hope that the total for the year will be not far short of the record of 7,980,000 tons in 1913. The Alberta collieries, ever seeking an expanded market, have virtually captured the Manitoba trade and are making

a bold bid for part of Ontario's custom. Building has recommenced on a moderate scale, so that the other principal non-metallics are in normal demand.

All told, the half-yearly summary of mineral production is a satisfactory and encouraging statement. But we must remember that the ground gained requires to be consolidated before it is secure in our hands; and no effort should be spared to reduce, by every possible means, the wild, pendulum-like swings that result alternately in hectic activity and stagnation. To eliminate this curse of modern industry is beyond the power of those of the mining fraternity; but the miners can at least do their bit in studying the problem and seeking a solution.

A PADRE IN THE MINES

Canon Scott's decision to visit the collieries and steel works of Cape Breton is worthy of our well known and respected soldier-padre. Military affairs have an irresistible attraction for the Reverend Mr. Scott, and when the active militia of Canada, almost in full force, gathered at Sydney recently, he simply had to join them in some way or the other. Unfortunately for him, the "enemy" was not susceptible to attack in the ordinary way, and the reverend gentleman, to participate at all, had to attack either the labour leaders or the management of the British Empire Steel Corporation. In choosing the latter against whom to aim his shafts, he was, we doubt not, influenced mainly by a feeling for the under dog. From our knowledge of the case we should judge that he did not know at what target he aimed, and certainly he missed the mark. We are satisfied that he has been grossly misinformed. Now he will find out the truth at first hand. If his attack should prove to have been unjustified, or justified only in minor degree, Canon Scott will hesitate not a moment to say so publicly, and in his usual forcible and unequivocal manner. We expect his report will go far toward overtaking the lies that have been spread during recent years by labour agitators in Nova Scotia. If he is able also to indicate any feasible means of improving still further the lot of the workman in Cape Breton, we are confident the Company, as well as the public, will thank him for his pains.

TONNAGE LOST IN COAL MINES

A new item of arresting importance is included for the first time in the report on coal statistics for May, issued by the Dominion Bureau of Statistics last week. This is the table showing the tonnage lost in Canadian coal mines due to absentee-ism, lack of orders, car shortage, mine disability and other causes. Similar information has been given for some time past in the weekly reports from Washington of the United States coal industry. This simple little table gives plenty of food for thought. During May, for instance, Canadian collieries lost 26 per cent. of their output, 15 per cent. of this being due to lack of orders, most of it in the three western provinces. The table will thus show up from month to month the chronic state of over-development in these provinces. During May a flare-up between manager and men at Minto, New Brunswick, brought the percentage lost by absentee-ism up to 12 per cent., the average for the Dominion being only 3 per cent. This information on the negative side of production will be a very useful barometer of events and tendencies in our colliery districts.

NEW DEPARTMENT WILL AID MINERAL DEVELOPMENT

Our railways require the aid of mineral development to make them pay and to keep them prosperous. Mr. W. D. Robb, Vice-President of the Canadian National Railways, made an anouncement last week bearing on this question. He pointed out that the National system has a newly organized "Department of Colonization and Development" at its headquarters in Montreal. It is an enlargement of the former "Industrial and Resources Department", formerly in Toronto in charge of Mr. C. Price-Green, who is at the head of the new department. The stated purpose of the department is to gather from all available sources information concerning the natural resources of the areas served by the railway with a view to passing it on to prospective settlers, prospectors and other pioneers of rural and industrial enterprise. The department will also give active aid to those interested in the natural resources through the numerous channels open to the railway man.

The chief sources of information concerning the Dominion's mineral resources are the various government departments. Besides published reports, these departments have a vast collection of useful data and ideas, on file and available to those who will enquire. The new branch of the Canadian National Railways aims to keep in close touch with these bureaus, both federal and provincial, and has taken practical steps to that end.

To supplement the data available from public departments, the Department of Colonization and Development of the railway has organized its own sources of information. From the officers and employees in the various central offices and scattered up and down the 22,000 miles of line much that is useful in stimulating development can be learned by the judicious enquirer. To collect and use these facts and ideas is now the specific duty of the new department.

Original and deliberate investigation at first hand can never comprise any large part of the duties of a department such as this; yet it may be a very important part, particularly in the case of the mineral industry. An unusually large fraction of the Canadian National lines will always depend primarily upon the mineral industry for local traffic sufficient to

make them pay. Apart from the four hundred miles where it traverses the Great Clay Belt, the Transcontinental from Quebec to Winnipeg will depend mainly upon the products of forest and mine for its freights. The same can be said of the former Canadian Northern main line from Sudbury to Winnipeg. In the West the growth of a large industrial community round the colliery districts will transform the balance sheets of all the sections of railway within their reach. The present mining activities in the vicinity of Smithers, British Columbia, promise to bring prosperity to that section,—an untravelled wilderness until the Grand Trunk Pacific was pushed through to Prince Rupert. The Pacific Great Eastern is typical of a host of small lines and branch lines from Atlantic to Pacific, now a burden on the public purse, and awaiting the efforts of the miner, lumberman or paper maker to provide them with an income. Officers of the new department are now at work investigating some of these prospective mineral fields at first hand.

One of the most important adjuncts to the development of a new mineral area is, of course, railway transportation. The Canadian National organization is now equipped, through its new department, to investigate promptly prospective mining camps with a view to constructing branch lines.

The Department of Colonization and Development has a task of prime importance to perform on behalf of the Canadian public. We are confident that, with sound direction and energetic performance, it will add much to the income of the Canadian National Railways.

BUBBLES IN IDAHO AND LABRADOR

The platinum fakirs in the Western States are having a thin time. A few weeks ago the United States Bureau of Mines exposed their fraudulent claims in a most conclusive manner. Now the Bureau of Mines and Geology of Idaho, connected with the State University, shows that without exception the supposed platinum mines of that state do not contain even a trace of the precious metal. In addition, samples from the promoters actually containing platinum have been shown by microscopic examination to contain it in the form of platinum foil. The names of the promoters from whom these salted samples were obtained, as well as of others connected with the illicit venture, are given plainly and the method of their deception described.

An accusation made against the public authorities by these swindlers—the same we have heard in Canada recently in conection with the alleged coal beds near Sudbury — is that they were leagued together against a company of honest miners. With this point in view, the Idaho Bureau of Mines submitted a full set of samples taken from the supposed platinum deposits not only to the highest authorities on such analysis in the United States, but to the Provincial Mineralogist of British Columbia and the Consolidated Mining and Smelting Co. at Trail. The assay returns from these foreign authorities agreed in every detail with those made in the United States.

Once more we point out that this plain and unequivocal statement by public authorities of their knowledge of a fraud is a most potent means of preventing its recurrence. There are plenty of similar frauds being perpetrated in Canada today. Cannot our public authorities expose them likewise? The Labrador bubble has burst. Might not a simple statement from Ottawa or from Quebec have pricked the bubble before it was swelled from the pockets of scores of victims?

HELIUM

The technical session in Montreal that terminates the ten-day tour of the American Institute of Mining and Metallurgical Engineers through the mining districts of Ontario and Quebec has much of an international character, both as to its personal and its programme. At the geology session there is a paper whose title might lead one to believe it is abstruse, but whose import is wholly practical. This is Dr. Richard B. Moore's discussion of helium.

It is less than thirty years since Sir William Ramsay first determined that the gas emanating from certain minerals containing uranium and thorium is the same as the gas that, with hydrogen, composes the outer reaches of the sun's incandescent atmosphere. Though so abundant in the sun, it remained a rare element on this earth until the last decade,, when a systematic search revealed its presence in amounts up to two per cent. in the natural gas of various districts of the United States and Canada.

So far as has been determined, helium forms no stable compounds; it is completely inert. It has a density of 1.98 ((hydrogen=1), so that its lifting power is only half that of hydrogen; but still it is only one-seventh as heavy as air. Its boiling point,, which is approximately the point at which it liquifies, is-268° Centigrade, very close to the absolute zero. The fact that the other gases mixed with it in natural gas become liquid at considerably higher temperatures is used for their separation. As the giant dirigibles now in use or under construction contain up to two million cubic feet of gas, one can gauge the vast amount of natural gas that must be treated before one of them can be filled with helium.

Dr. Moore says the United States has virtually a monopoly of the world's helium supply. Only two small sources are known in Canada, one in Ontario and the other in Alberta, containing 0.34 and 0.33 per cent. helium. As yet we know very little about the natural gas resources of Alberta. Their development may quite possibly provide a helium supply for the British Empire.

Canada and the Imperial Economic Conference

By A. R. R. JONES, Editor, "Journal of Commerce."

The Imperial Economic Conference will assemble in a very few weeks, and the Canadian representatives will shortly be leaving this country to attend the same. A great opportunity is offering for the solution of Imperial economic problems in such a way as to increase the prosperity, the unity and the security of the whole British Empire. One trusts — profoundly trusts — that the representatives of all the nations which compose our world-wide Empire will have the understanding and the wisdom to avail themselves to the full of the opportunity which offers now, and which, if lost, may not lightly be recovered.

The present writer has frequently pointed out why it is particularly essential just now that every effort should be made to foster and stimulate inter-Imperial trade, and he has no intention now of covering that ground again. He has never urged that any one part of the Empire should sacrifice its own commercial and industrial interests to those of any other part. Great Britain is a great manufacturing country, and the overseas Dominions — and notably Canada — are developing their own manufacturing industries with speed and success. Yet there is no part of the Empire which can be said to be self-supporting in the matter of commodities. Each is under the necessity of importing products from outside its borders. Such products, with very few exceptions, are obtainable elsewhere within the Empire.

The objective to be aimed at, then, is for citizens of the Empire to buy Empire-made goods — for Great Britain to buy all she needs, and cannot herself supply, from within the Empire and for every other nation of the Empire to do the same. But the Imperial Economic Conference must give a definite and unequivocal lead — must devise the means for the consummation of this highly desirable end.

So far as Canada is concerned, her position, by reason of her proximity to the United States, is different from the other countries of the Empire in this matter of inter-Imperial trade. More than one-half of Canada's trade is done with the United States, and, next to Great Britain, she is the best customer the United States has. With the Fordney tariff erecting a barrier against Canadian products, it is likely that Canadians in general would welcome Empire-produced goods in preference to those produced in the United States, provided always — and the proviso is a substantial one — that the price and quality are equal.

There is one matter, to which I have adverted before, as to which I trust that our representatives at the Imperial Economic Conference will speak plainly when face to face with the representatives of Great Britain at the Conference table. Here in Canada we are rapidly becoming a manufacturing country of considerable importance. But we need outside help in developing our manufactures. At the present moment, that help is mainly coming from the United States. It is up to the British to change this — to aid in the development of Canadian industry to a far greater extent than they are doing.

A recent estimate places the United States capital invested in Canada at $2,500,000,000, or almost as much as the British investment in the Dominion, and the greater part of this investment (approximately $1,750,000,000) is estimated to have been placed since the pre-war period. Statistics recently made public by the Canadian Pacific Railway indicate that United States investors now hold $701,000,000 of Canadian government, provincial and municipal issues, as against $511,000,000 held by British investors. In other words, United States investors hold 18.5 per cent. of the total amount of the above issues compared with British holdings of 12.8 per cent.

The showing relating to investment in Canadian industrial enterprises is even more striking. United States investment is estimated at $848,455,589, or 31 per cent. of the total investment, and the estimate of British capital in these enterprises is $285,153,175 or 10.3 per cent. of the total.

United States capital has gone into Canadian railways, mines, motor car and accessory industries, meat-packing, rubber, paint, metal, pulp and paper, and refined petroleum industries. The Canadian Pacific Railway estimates that 24.1 per cent. of its shares are owned in the United States as against 47.8 per cent. held by British investors and presents these figures as typical of the direction of outside investment in Canadian railways. It also reckons that United States investors hold 32.36 per cent. of securities of Canadian mines whereas British investors own 15.46 per cent. It is notorious that the Canadian motor car accessory industry has drawn practically all its capital from the United States. The United States also has contributed 80 per cent. of the capital invested in the Canadian pulp and paper industry, 61 per cent. to the motor car industry, and 40 per cent. to such important Dominion enterprises as the meat-packing, rubber, and refined petroleum industries.

Figures such as those we have given should cause leaders of industrial and economic thought and activity in Great Britain seriously to ponder the situation in which Canada finds herself in relation to

Great Britain, on the one hand, and the United States, on the other. We are not among those who believe that Canada's loyalty to the British Empire is so skin-deep that it can be deflected by any trade, on however large a scale, with a foreign country. But, none the less, save in a purely material sense, it is not altogether well for Canada for a foreign country to have almost a predominant stake alike in our public issues of securities and in our private industrial enterprises. Nor, should we imagine, is such a state of affairs altogether well from the standpoint of Great Britain herself. If it is not, the remedy is in the hands of her financial and industrial leaders.

Incidentally, it may be added that not only capital is being contributed by the United States to the development of Canada's wonderful resources. Accustomed to great movements of population from Europe to the United States one is apt to overlook the fact that there is a country into which large numbers of the United States' own citizens find it desirable to emigrate. Total immigration into Canada in the years 1900 to 1922 was 3,667,310 and more than one-third of that number were from the United States. In fact the emigrants from that country numbering 1,395,853 exceeded the number of British emigrants to Canada by more than 30,000. When note is taken of this circumstance, coupled with the important position the United States has assumed in relation to Canadian industry and finance, we imagine that the significance of the conjunction cannot fail to be apprehended in Great Britain.

MINERAL PRODUCTION OF CANADA FOR THE SIX MONTHS ENDING June 30, 1923

A report on the mineral production of Canada for the first six months of 1923 has just been issued by the Dominion Bureau of Statistics. This report shows that the mining industry has recovered almost entirely from the slump of the last few years. The production of the mineral commodities covered amounts to $87,152,248 in value as against $60,361,109 for the same period last year, an increase of 44 per cent. The production of metallic minerals is valued at $39,244,614, while that of the non-metallics amounts to $47,907,634. These show increases of 48 per cent and 41 per cent respectively, the corresponding productions for 1922 being $26,475,544 and $33,885,565.

In the metallic section the outstanding increases were in the production of nickel and copper. The surplus stocks existing at the end of the war seem to have been absorbed, and from now on a steady production is looked for. The increase for the full year promises to be still greater, as one large potential producer did not start operations until well on in June.

The gold mining industry is in a satisfactory condition, although the production shows a slight falling off from that of the corresponding period last year. This was due entirely to the prolonged power shortage in Porcupine this spring, a dry fall followed by a late breakup of ice on the lakes and rivers proving a severe handicap to the power companies. With increased crushing capacities, and one new producer assured, it is expected that the 1923 total will equal that of 1922. The gold production of Canada for the first six months of 1923 amounted to 530,402 fine ounces valued at $10,964,382.

Silver production also showed a slight falling off when compared with that of the same period in 1922. However, the outlook for this industry is particularly bright for the latter part of the year. Large shipments during the summer from the new silver mining districts of the Yukon will undoubtedly make up for any declines in production from the older camps. During the first six months 8,336,946 ounces valued at $5,506,469 were produced contrasted with 8,905,454 ounces valued at $5,997,199 in 1922.

The other metals all showed increases in production compared with the same period last year.

The section dealing with coal contains comparative tables on the more important statistics pertaining to this commodity. The production amounted to 8,722,205 tons valued at $38,188,343 as compared with 6,205,288 tons valued at $26,993,498 for the first six months of 1922. The increase amounts to 2,516,917 tons valued at $11,194,845 or 40.5 per cent in quantity and 41.5 per cent. in value.

Increased production is general throughout the list of non-metallics, the most important increase being in asbestos. To the end of June, 99,042 tons were sold by producers for $3,574,762, as compared with 54,846 tons and $1,894,232 during the same period in 1922.

Copies of the report may be had on application to the Dominion Bureau of Statistics.

SIR ALFRED YARROW'S GIFT FOR RESEARCH

The Council of the Royal Society have of late been giving their attention to the best way of using Sir Alfred Yarrow's gift of £100,000 for the endowment of research, which was announced in February of the present year. On reviewing the situation, it appeared to the Council of the Royal Society that there was a marked deficiency of positions in which a man who had already proved his capacity could continue to regard research as the main occupation of his life. Consequently, at the council meeting of July 5, it was finally decided to use the larger part of the income in the direct endowment of research by men who have already proved that they possess ability of the highest type for independent research. To this end a number of professorships will be founded, of a type similar to the Foulerton Professorships, which were founded by the society in 1922 for research in medicine. The professors will be expected to devote their whole time to scientific research, except that they may give a limited course of instruction in the subjects of their research to advanced students. There is at present a tendency to regard scientific research as a secondary occupation for men whose primary occupation is the teaching of students. The intention of the Royal Society in founding these professorships is to recognize research as a definite profession. — "The Chemical Age".

ALCOHOL AS MOTOR FUEL

The use of alcohol as a motor fuel is gaining ground rapidly in South Africa. It is used there in admixture with ether made from it, the trade name being Natalite. Though it will not give a mileage equal to gasoline, it is much cheaper, — 2s. 3d. against 3s. 6d. at present. In running it is at least the equal of gasoline.

Depletion Allowance in Mine Taxation

Mining Association of British Columbia Studies the Problem

By H. G. NICHOLS

The general understanding of this subject has not been assisted by the loose employment of terms. For instance, a comparison has been made between the words amortization and depletion. The definition of the former is "the extinction of a debt by a sinking fund;" the latter means "the act of emptying out." The problem associated with the matter of depletion allowance is to know what is the fairest way in which to provide for the fact that mines are being emptied out, and it is clear that the principle of amortization might be applied in carrying out any process to this end; but that is a small matter compared with the question of what is the right process to adopt.

Depletion then is an accepted fact; how to make allowance for it is a burning question.

To begin with, the State has vested interests in its mineral deposits, and if there were no risk attaching to their commercial realization it is conceivable that it would proceed to exploit them. However that may be, the fact is there is a risk, and the State is willing that it should be assumed by Capital. Further, it is in the interests of the State that Capital should be encouraged to assume the risk, to the end that the State may participate in the returns. Now the risks vary and cannot be assessed without the expenditure of Capital; therefore as between the State and Capital it becomes a question of encouraging Capital to try its luck. Insofar as participation in the return from its mineral assets is concerned, the only method so far devised is to impose a tax on income, so that looking at the matter broadly the problem becomes one of adjusting mine taxation, in such manner that Capital may have sufficient inducement to face the indeterminable risks and the inevitable disappointments attaching to the exploitation and development of a Mining Industry.

In other words, the State is bound to protect Capital; it does not want to see Capital lost, because it is only Capital that can keep hammering at the risks and making a profit for the State; and if it is exhausted the Mining Industry gets a black eye. Consequently once a fair royalty or tax upon income has been decided upon, applicable to successful operations, it becomes a question of how much that tax should be reduced in order to protect the Capital involved in the perpetuation of the profit. That is where the question of depletion comes in; the mine is being worked out and the whole cycle of risks must be faced again.

Stated thus, the matter does not seem to be so complicated; but the realization of the facts upon which the calculations must rest has come about only as the result of hard experience and much intensive study on the part of those who have assumed the task of finding an equitable arrangement.

Mining Association and Government Confer

During the past year the Mining Association of British Columbia, under the guidance of the Secretary, Mr. H Mortimer Lamb, has been active in inducing the Provincial Government to consider the problem, and to establish a system whereby a due allowance for the wasting nature of mineral assets may be provided for in the matter of taxation.

A conference was held at Victoria in December 1922 between the Hon. Minister of Finance and representatives of the Mining Association, when the Minister invited the co-operation of the Association and of others interested, and suggested the forming of a Committee consisting of Government officials and representatives of the Association. At that time the calculation for depletion allowance was generally supposed to depend upon the valuation of the property, to the end that a unit charge upon the mineral produced would offset ultimately the outlay or the value of the property calculated as at some set date. The difficulties of applying any such principle to the cases of unproven mines gave rise to a great deal of discussion of the fact that the difficulties already experienced in the practical application of this method in the United States would surely be greatly enhanced in the case of a country such as British Columbia.

Dr. Graton Studies British Columbia Problem

In order that the full benefit of previous experience might be obtained in carrying on this discussion, Mr. Mortimer-Lamb submitted the whole problem to Dr. L. C. Graton, and the subsequent discussion was greatly benefitted by Dr. Graton's public-spirited response. Dr. Graton said:

"If taxes are to continue at their present heavy rate, and if the mining industry is to survive under the burden, it will be necessary, in my opinion, to grant depletion as an annual deduction regardless of whether the total previous depletion deductions may have equalled already the original purchase price of the property or some valuation put upon it at some preceding date. Since the fundamental object of depletion is to return to the tax-payer exempt from tax his original capital value in the property, it might seem on first thought that when the total of this capital value has thus been reached through the accumulation of annual depletion deductions, he should be entitled to no further depletion. But as everyone who understands the mining business realizes, for each productive mine there have been many prospects into which money has been put, but which have returned little or none of it, but the investigation of these numerous cases that eventually proved to be failures was a necessary part of the process by which the relatively small number of successful mines was found. If the losses involved in the failures have to go unrequited from the tax standpoint, and if all the profit from the few successes is taxed heavily after the cost or value of that single success has been returned by depletion, the mining business as a whole,—which is and always must be a mixture of many failures and a few successes,—will languish; the business of ore-hunting will be abandoned, and only those new mines that are discovered by merest chance will come to light, and the number of those will decrease steadily.

Depletion Allowance Should Remain as Long as Mining Continues

"Specifically, then, my feeling is very strong that depletion should be maintained so long as a mine is productive. Let us assume that a given property was purchased five years ago by the present owners for a million dollars, and let us assume that the price then paid was a fair price as judged by the apparent ability of the mine at that time to yield profit. Suppose the mine since that time has produced all the ore that at the time of purchase it could be estimated to contain, and that the profit

realized from the production since purchase has actually justified the purchase price. Theoretically, then, the mine ought to be just exhausted and if it has been paying tax and been receiving the benefit of depletion deduction based on cost, then the total depletion deduction so received should now exactly equal the purchase price.

"But suppose instead of being exhausted, the mine now contained as much ore with as great a prospect of profit as when it was purchased five years ago; in other words, the enterprise, intelligence and courage of the management had brought to light new ore that could not properly be included in the valuation five years before. In such a case, the mine will continue to produce after all its depletion based on purchase price has been used up, and will have to pay a tax on its full income without depletion.

"Alongside of it there may be a mine having ore of the same grade and character and capable of extraction at the same cost. This second mine may have been purchased only recently and therefore still possesses a depletion reserve based on cost. The two mines will therefore have to pay on a wholly unequal footing. The first mine will have to pay a tax on its entire net income without depletion, the second will deduct depletion before computing the tax.

"It is idle to argue that a case of this sort is sound and fair, yet cases of this sort are bound to arise frequently, because mines can never be fully measured as to value at any given time. There is always the possibility, and in many cases the probability, that the measurable reserves to-day will be greatly exceeded in the future.

"There is only one way to obviate this unfair distribution of the tax burden, namely, by granting depletion steadily as long as production is maintained. Intelligent and fair-minded analysis of such a program will show that there is nothing unfair about it either within the mining industry or to taxpayers outside that industry.

The Problem of Valuation

"The difficulties of valuation for purposes of taxation have been found to be such as to lead to results that are never satisfactory; that necessitate repeated and frequent adjustment, and that cost for their administration a sum wholly out of proportion to the requirements of the case. If some simple or more or less empirical method of computation of depletion allowances could be arrived at, many of the difficulties of administration would be eliminated. The suggestion has been made frequently that a flat rate of depletion of so many cents per pound or per ounce of metal be given to all producers. Two cents a pound for copper would be a fair depletion for some of the long-life porphyry mines in which the actual present value of the profit per pound is low. Two cents, on the other hand, would be an inadequate depletion for some rich mines of relatively short life. This scheme, therefore, while possessing certain advantages of simplicity, is inequitable.

"The simplest scheme of all, and the one that approaches closest to an equitable distribution of the tax burden, is to allow as depletion a given percentage of net operating income each year. Detailed investigation of the relation between operating expense and selling price and the ore reserves capable of estimation, of all the important copper properties owned by companies incorporated in the United States, indicates that if the annual depletion allowance be put at 33 1-3 per cent of the net operating income, just about the same results will be achieved in the long run as if exhaustive valuations were made for each property. The consequence of such a method of depletion determination would in the first instance be this:—Suppose copper sells for an average of 16c a pound during a given year and suppose the operating costs of production for a given company average 10c per pound, leaving a net operating profit of 6c per pound. One-third of this granted as depletion, or 2c per pound would leave 4c from which to deduct depreciation which might be, say 3-4c, the tax to be paid on the balance of 3 1-4c. A Company, then, producing 10 million pounds with a net operating expense of $600,000 would be granted $200,000 of that as depletion, $75,000 as depreciation and would pay tax on $325,000. If during the next year the price of copper should increase to 20c while the costs of production, which lag behind the changes in selling price, increased to only 11c a pound leaving a net operating profit of 9c, depletion would increase to 3c a pound, depreciation would remain at 3-4c and a tax would be collected on 5 1-4c of profit. On the other hand, in a year when the selling price declined to 12c and costs could not be reduced below 9c, giving a net operating spread of 3c, depletion would be 1c a pound, depreciation still 3-4c and the tax would be paid on 1 1-4c of actual profit.

Depletion Allowance of 33 1-3% of Net Operating Income is Fairest to All

"This would mean that in periods of normal profit mining companies would pay a normal tax. In years of high profit they would pay a high tax, but they would also, as is proper, actually or theoretically accumulate a larger sum for their depletion reserve. In periods of low profit they would pay a lower tax and likewise put by a smaller depletion reserve. This is all as it should be, in accordance with sound economics. Furthermore, suppose that by the present scheme of basing the depletion allowance on cost or valuation, a given company has a depletion allowance of 3c per pound. If the difference between operating cost and selling price is fairly small, the company's operating profit may actually be insufficient to cover its depletion and depreciation and, therefore, it would pay no tax. In the case, therefore, of a government dependent in considerable measure on the tax it collects from the mining industry, the Government might receive no tax whatever from that industry in periods of fairly low prices, even though the mining companies were actually making some money. The plan of charging depletion on the basis of a percentage of net operating income serves the advantageous purpose of equalizing the high points and the low points, giving a reasonably steady income, and imposing on the taxpayer a burden fluctuating less widely.

Scheme is Simple and Economical

"The scheme has one other enormous advantage from the standpoint of administration. It is a fairly simple matter for a tax bureau to ascertain the total receipts and the total operating expenses of a given company,—in other words, to ascertain the net operating income. It is a far more difficult matter to administer depletion as it is being handled in the United States at the present time. Depletion without the benefit of discovery will soon put an end to the mining business if taxes continue to be heavy. The administration of the discovery clause in the United States law has already almost wrecked the Revenue Bureau and has worked great hardship on many Companies. All this trouble and effort would be eliminated by the percentage method. The year's balance sheet would suffice for everything and a simple computation would clear away the question of depletion, I believe to the satisfaction of all concerned.

"Mr. James C. Dick, who was for a considerable length of time in charge of all the mine valuation work in the

United States Revenue Bureau, is thoroughly convinced, as I am, that the method of computing depletion as a fixed percentage of operating income is the simplest, fairest and best method. Mr. J. A. Grimes, at present a member of the Revenue Bureau in Washington, who has given more thought than anyone in the Bureau to this problem of mine valuation for taxation purposes, also favors the percentage method, primarily from the standpoint of simple administration and also as the simplest method of obtaining fair play for all concerned."

Dr. Graton Explains 33 1-3% Depletion Allowance

The recommendations embodied in this letter were submitted in the first place to every mine operator in the Province, and were accepted unanimously. They were then submitted to the representatives of the Finance Department of British Columbia at a metting held at Victoria in February last, and it is not surprising perhaps that immediate recognition of the advantages to be obtained by the depletion percentage method was not realized. The Government in fact asked for an explanation as to how the arbitrary rate for depletion of 33 1-3 per cent of the operating income had been arrived at; how it could be shown that the method would apply equitably in the case of all mines, and whether the revenue derivable by the Government under this system would be less than if either the cost or valuation system were employed. These questions were referred by Mr. Mortimer-Lamb to Dr. Graton, who replied as follows:—

"The figure of 33 1-3 per cent. for depletion was arrived at in this way:—Very complete data of all copper companies that had yielded a profit over a considerable period of years were on file in the Bureau. From these data, supplemented in a great many instances by much further correspondence and by many personal interviews with engineers or managers of the companies, valuations were arrived at for the purposes of depletion, and in this way a depletion allowance per pound was established. To arrive at the valuations it was necessary, of course, to determine the estimated average operating profit per pound. A comparison, individually and in the aggregate, of the relations of the depletion allowance and the operating profit (which relation would be the depletion percentage) indicated a maximum range, as I recall it, of some 21 per cent. to 47 per cent,—the lowest figure applying to a property having such a vast tonnage of ore developed that only such portion of it as would probably be mined in the next 40 years was assigned any value whatever, and the highest percentage applying to a mine already practically exhausted and possessing at that time a richness of ore which probably had never been equalled by an important producer theretofore. These two extremes were so decidedly extreme that similar examples would rarely be encountered. As a matter of fact neither of these mines is within the United States and one of them is not on the North American continent. The great majority of the mines investigated were found to fall within the range from 25 to 40 per cent. and there was a striking concentration in the range from 30 to 35 per cent.

"The general field of silver, lead and zinc mines was also studied, but not as thoroughly as in the case of copper. Some of the small, short-life zinc properties in Oklahoma gave percentages running into the 40's, and I believe one or two exceeded 50 per cent; but in general an average in the neighbourhood of 33 1-3 per cent. seemed fair. So far as I recall, no analysis was made of the situation with respect to gold mining.

Difficulties of Individual Valuations

"It is, of course, evident that a fixed rate will apply exactly to very few companies, if any; some ought to have more, some less. The whole question hinges on whether the degree of inaccuracy involved in the assumption of an arbitrary flat rate is sufficient to balance the difficulties and delays and the added expense both directly and indirectly, to taxpayer and to government in endeavoring to arrive at specific valuations and depletion allowances for each individual case. My own experience has led me to conclude that there is no feasible middle ground; one extreme or the other must be adopted. If certain mines were to be put in a 40 per cent. class and certain others in a 30 or 25 per cent. class there would be a perpetual squabble with respect to the innumerable border line cases. The classification you say the Dominion Government has adopted undoubtedly does permit the application of different percentages without much difficulty, though I should be interested to know how a mine would be treated that produces copper with silver as an important by-product. Furthermore, in this instance I feel confident that if the Canadian copper mines are on similar footing with those in the United States, a 25 per cent. average depletion is too low for them when considered in comparison with the entire exemption of cost of raw materials for other industrial enterprises. Moreover, the distinction made between gold and silver mines, on the one hand, and copper mines on the other, of course, works out to increase doubly the burden on the copper mines; not only is a larger proportion of their annual income subject to tax, but the tax they have to bear is larger also because of the failure of gold and silver mines to have paid a proportionate share toward the total.

"As a rule the shorter lived mines, to which, other things being equal, a higher percentage of depletion should apply, commonly prove to live longer than the time that could fairly be assigned to them on the basis of ore reserves at any specific time. On the other hand, mines of very long life, for which a lower depletion rate might seem proper, generally operate on a low margin of profit and therefore are likely to be very seriously affected by adverse market conditions or by any slight failure to realize the estimates; there is, in consequence, an element of hazard that attaches to their enterprise quite as much as that which hangs over the short lived mine. A depletion rate too low would fail to take proper account of this feature.

Percentage Method Gives Fair Average Valuation

"The percentage method of computing depletion operates to correct automatically any errors that might be involved in valuations upon which the particular percentage figure is based. Suppose, for example, that in the case of a given mine the estimates of cost, selling price, tonnage and grade of ore, and life were such as to indicate an operating profit of 6c per pound on copper and a depletion allowance of 2c. If all of the estimates used in reaching these figures should prove in the course of time to have been correct, then a depletion allowance of 2c per pound would have been exactly fair; but if the grade of ore actually turned out to be higher than had been estimated, or the average selling price greater, or the operating costs less, then a 2c depletion per pound would not have been fair; a higher figure should have been granted. On the other hand, if the grade of ore was less than had been estimated, the costs higher, or the average selling price lower, then 2c per pound would have been too large a depletion.

"If, on the other hand, instead of using the 2c depletion rate, the ratio of this to the operating profit of 6c—namely, 33 1-3 per cent.—had been used as the depletion factor and applied to the operating profits each year, then practically all the errors involved in the original valua-

on would be adjusted automatically so far as depletion concerned.

ercentage Method Gives Steadier Income from Taxes

"With regard to the actual amount of revenue the rective systems would yield, it is probably impossible to peak with precision. The method of individual valuaons and of specific depletion allowances in cents per ound or ounce will yield the estimated income only in year when the actual outcome with respect to selling rice, cost, production, etc., accords exactly with the averges used in the valuation. In years when the profit to ne companies is greater than the average so estimated, he tax will be high because the depletion allowance is ixed. On the other hand, in years when the profit to he companies is less than the estimated average, the tax eceived by the Government will be low for the same reaon that the depletion is fixed, and when the operating profit equals or is less than the depletion allowance there will be no tax whatever.

"With the application, however, of depletion on the percentage basis, revenue to the Government will be much more even, and this undoubtedly is highly desirable. In the average year (if such a thing ever happens) the tax will be exactly what was estimated. In years of high profit the tax will be greater, but not so much greater as by the specific depletion allowance method. In lean years the tax will be correspondingly lower than the average but not so low as by the specific depletion allowance method, and the Government's income will never be zero unless the mines earn no operating profit whatever. This smoothing out of the extreme fluctuations in the tax burden on the mines and of the revenue from mines to the Government—fluctuations that are likely to be on the whole greater for the mining industry than for almost any other—is, I believe, one of the principal advantages of the percentage method.

"Unfortunately I cannot give you specific figures as to the actual comparative advantages of the two systems from the standpoint of the Government, principally because no such figures exist; but if one will take into account the great expense of administration by the method that demands individual valuations, it seems that he cannot fail to believe that the Government will be far better off in the long run if it adopts a simple percentage method.

Dr. Graton Commends Association's Effort Toward Uniformity

"It seems to me that your associated companies are exceedingly wise in agreeing to a common basis for the common good. I believe that if their position should be accepted by the Government, the net amount of tax secured by the Government over and above the expense of collecting it will be greater; yet the tax burden to the mines will be less than if an effort is made to arrive at a more precise determination of the tax in each individual case. If a depletion percentage were to be adopted now, the troublesome matter of depletion would be practically solved for all time; but on the other hand, as the experience in Washington has clearly shown, an attempt to compute the specific depletion for each company, although it would appear to be settled once and for all, as a matter of fact is never settled. Individual companies have had conferences with the Government officials almost without number. There have been in addition at least five or six hearings on the subject of depletion, and now the Bureau is preparing to reopen the entire matter and make radical changes in the basis of computations that were previously established;— in short, to tear down all that has been accomplished and build up a new structure. This not only costs money directly to the government and to the taxpayer, but it aggravates what is probably he most unfortunate feature in the whole field of taxation, namely, uncertainty."

The Search for a Satisfactory Method

The whole question was discussed again at a meeting with the Government officials in July last. The upshot of this investigation to-day is that the Government of British Columba has decided to adopt for the present the Dominion system of taxation in relation to depletion. pending future arrangements by which it may be possible to arrive at some uniform method.

The above is, in brief the history of an active campaign carried on by an organization that is justifying its existence in a way that is an example to others. The subject is an interesting one, and it is one that concerns not only British Columbia but the whole of Canada at a time when outside capital is being sought for the expansion of the country's mineral industry. It is hardly correct to say that the industry is being taxed out of existence; but on the other hand the advantages assured by the evidence of sympathetic treatment by the Government in the manner of taxation cannot be too greatly stressed in its importance to the arousing of outside interest. As has been pointed out, it is the mining industry as a whole that is to be considered. It has been said truly that the original attitude adopted by the Mining Association of British Columbia was to take the fullest advantage of previous experience.

The United States has taken the lead in this matter of depletion allowance, and has done valuable pioneer work, looking to a reasonable solution of the problem. With a degree of thoroughness that reflects the greatest credit upon the whole organization concerned, the efficacy of the cost or valuation method has been probed to the uttermost, and the machinery for its application has undoubtedly afforded an example of meticulously careful organization. It has, however, proved to be cumbersome, it has failed to achieve satisfactory results, and it has given rise to a great deal of ill feeling and dispute. In other words, the valuation of mines as at any specific date is too costly an experiment for any Government to undertake, and if some fair compromise can be arrive at, the experience of the past is sufficient to point to the advisability of its adoption.

Dominion Regulations

In its recognition of this fact the Dominion Government is to be cogratulated, and in the system it has adopted it has gone a long way towards what would appear to be the best solution of the difficulty. In its differentiation, however, as between gold and silver mines on the one hand, and mines of the baser metals on the other, there would appear to be a gratuitous invitation to trouble. Take, for example, the mines of British Columbia,—these certainly can not be classified as between gold and silver mines and base metal mines, for there are gold-copper deposits and silver-copper deposits in addition that would provide notable exceptions in the application of the arbitrary distinction. The Dominion Government regulations allow a deduction of 10 per cent. for depreciation There is an additional deduction from the remainder of 50 per cent in the case of gold and silver mines, and, in the case of baser metal mines, 25 per cent., of the net operating income, as being tax free as an allowance for the depletion of the mines. The only excuse for this differentiation is that the baser metal mines might be considered to have a longer life than the gold and silver mines; but, especially in view of the lack of clear defini-

tion between the classes above referred to, this distinction is not really practicable, and further it is very doubtful whether it would react to the benefit of the Government or not. On the whole, therefore, it would appear that the adoption of a Dominion-wide regulation by which 33 1-3 per cent. of the net operating income from mining operations is considered as being tax free in recognition of the wasting nature of mineral assets and the well-known risks of mining, is the fairest and most attractive tax regulation at which a Government interested in the promotion of its mineral industries could possibly arrive.

The progress of the above investigation has been trace in some detail to show how this idea of depletion cam into the calculations, and how the percentage deductio from income has been arrived at; but the whole matte resolves itself into a recommendation to the State tha income from mining operations should be taxed at a re duced rate of 6.66 per cent. for the purpose of encourag ing capital to run the risks of developing our mineral re sources.

The Uses of Concrete In and Around a Coal Mine

I — Surface Structures

By LUKE LINDOE*

I have been asked by the editor of this magazine to write a brief article on "The uses of concrete in and around coal mines". At the outset I would say that the writer is more familiar with the actual construction details than with writing about them, and doubtless among the engineers who read this article there is a large percentage who, on being asked to perform a similar task, have been confronted with the same difficulty of putting down in readable form the things they do and see every day of their lives. However, it has to be written, and it is hoped the brevity will conceal the journalistic inability of the writer.

Concrete has become, in recent years, one of the most valuable construction materials we have, in every phase of industry, and it is probable it will be used eventually in the mining industry as fully as in any other. Indeed, when one looks around a modern mining plant he finds that its adaptation here has probably kept pace with that in any other enterprise. Its variety of uses under a diversity of conditions, its comparatively reasonable cost and the ease with which it can be placed, offers the mine operator a real service, which he has not been slow to grasp.

In an article of this length only the uses of concrete in cases peculiar to coal mines can be discussed; but it should be mentioned that the structures above ground are usually designed to conform to standard requirements for similar buildings at other industrial plants. Warehouse, oilhouse, hoist houses, etc., follow closely

* Engineer, International Coal & Coke Co., Coleman, Alberta.

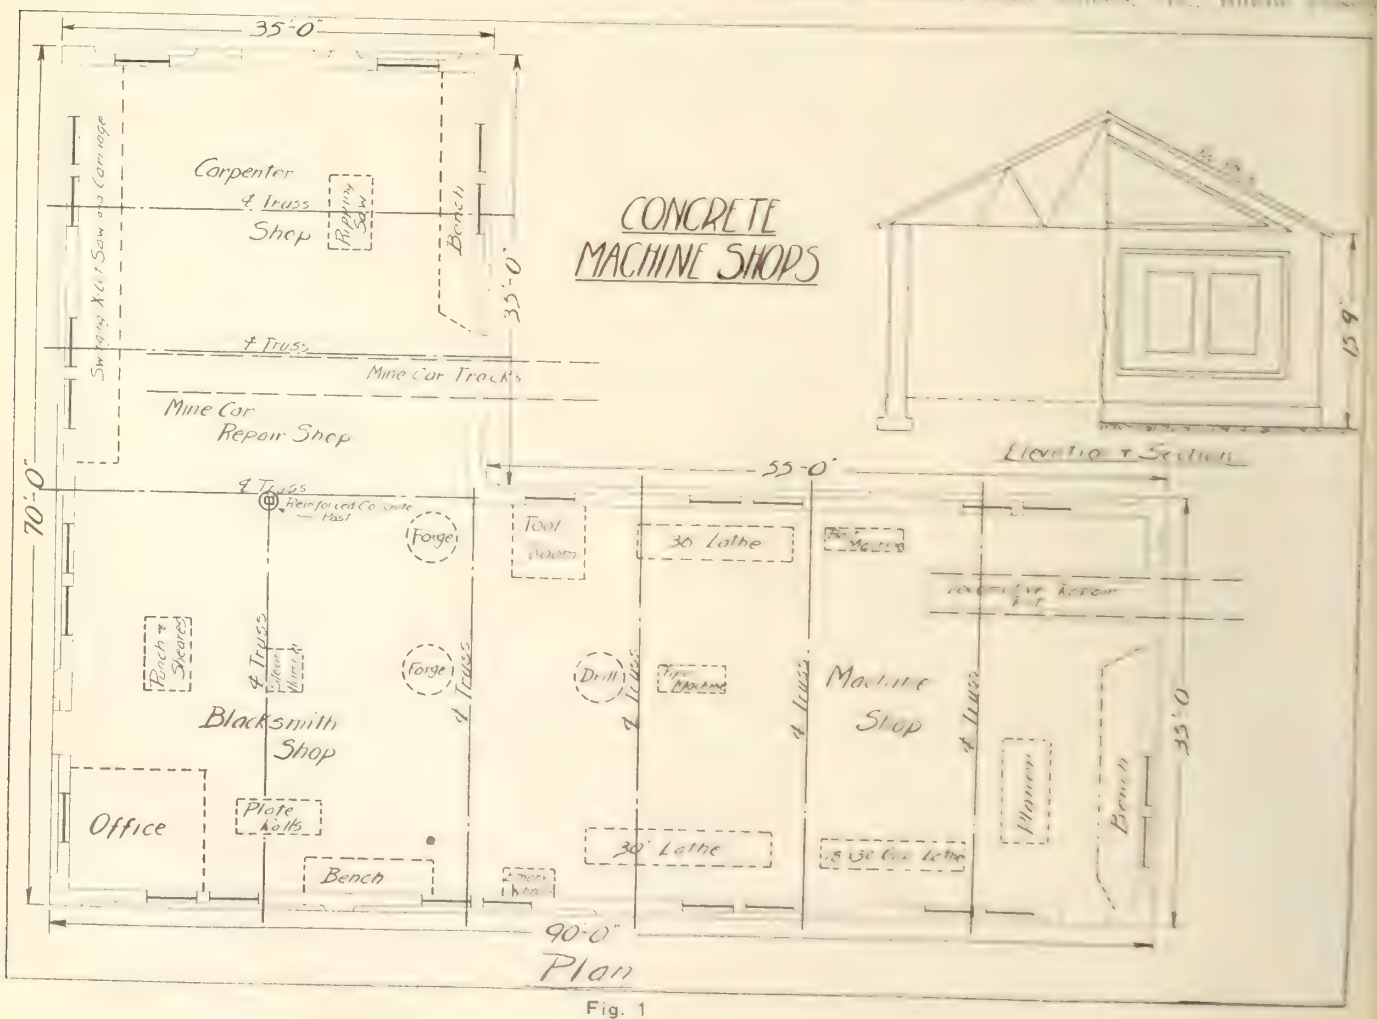

Fig. 1

the one-story factory design found elsewhere. On account of the limited requirements, the blacksmith, carpenter, electrical and car repair shops are placed under one roof. A typical layout is shown in Fig. 1. In this building, light steel trusses support the large spans, the roof proper being galvanized sheets laid on 1½" planks.

The buildings deemed peculiar to coal mines, though found elsewhere, are fan houses, powder magazines, bath houses, lamp houses and tipples. In the case of the last, local conditions and market affect the design to such an extent that no description will be attempted, the design usually being left to the specialist in this line.

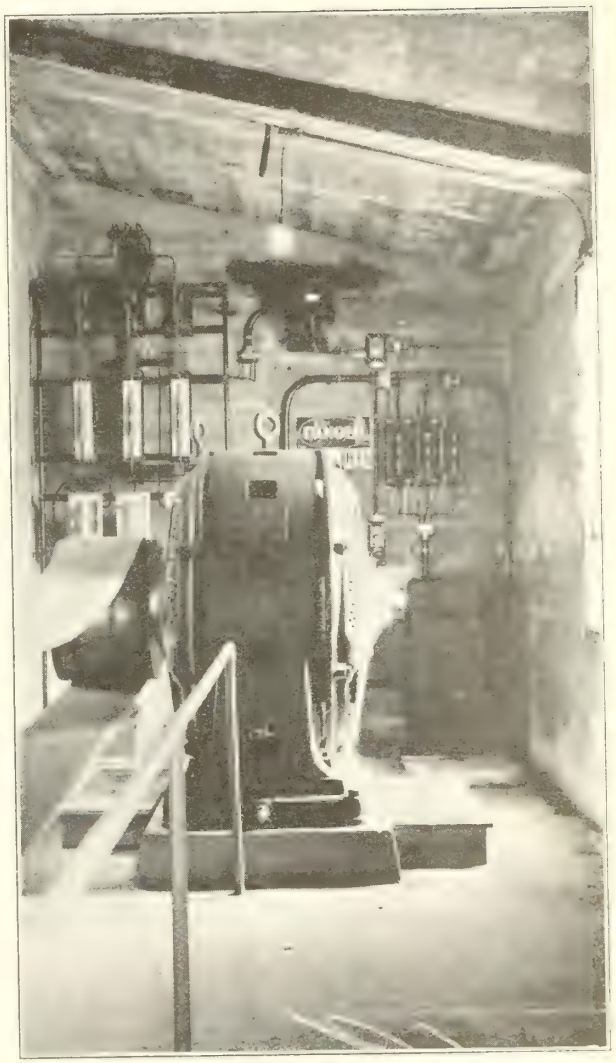
The tipple is probably the most important unit in the surface plant of a mine, as any cessation of operation here will affect the whole operation. It is for this reason that concrete and steel is replacing the old timber type of a decade or two ago, — promoting the longevity of the structure and the continuity of operation so necessary in this important unit of a mining plant.

Fan Houses

In the past, fan houses, fan drifts, etc., have been built usually of brick or stone, and in some cases even of wood, and while fine structures of this type can and are built, they develop faults not common with concrete, which prohibits them from being classed as ideal for this type of building. Often through age, settlement and cracking of walls or the use of poor or wrongly applied mortar, the joints between bricks or stones become leaky, permitting short-circuiting and wastage of air, with a consequent loss of efficiency in the fan. Not only is the air wasted, but the walls, once weakened by the loss of the adhesive properties of the mortar, are difficult to maintain intact.

Concrete lends itself admirably to this type of building, as fan drift, fan house, motor house, air-locks etc., can be cast as a monolithic mass and therefore are airtight and enduring. Little or no wood need be used in conjunction with it, — a valuable feature when a fan is placed, as it usually is, in an isolated situation in wooded areas where fires are a constant menace. There are no excessive load strains on the superstructure; the walls can therefore be kept light, placing the cost on a comparable footing with any other materials, considering durability, efficiency, and fire hazard

Concrete Fan House



Motor Room of Fan House

The accompanying photographs show a recent installation at one of the large western mines, designed to comply with the Alberta "Mines Act", whose regulations require that the fan be placed at one side of the line of the mine airway. To fulfil these requirements a 45 deg. deflection horizontally and a 30 deg. deflection vertically was placed in the fan drift, thus placing the fan itself well out of line of the force of an air blast should an explosion occur. Explosion doors are placed at this intersection to break the force of the blast. The walls are of plain concrete, 10" thick, resting on adequate footings, these footings being stepped where the drift conforms to the 30 deg. pitch of the seam. Roofs are of 6" reinforced slabs, with ⅝" bars turned at the ends and projecting into the walls and spaced 9" centres. On the fan drift roof, since the span is rather wide, the roof is given a camber of 6".

For the repair of old brick or masonry fan drift walls that have commenced to disintegrate and have become leaky, as mentioned above, cement mortar applied with one of the compressed air machines now on the market, offers an easy and economical means to the end. Sections of the wall are picked out, removing the old mortar

to a considerable depth, and these joints are then forced full of the cement mortar. The wall surface is also covered to a depth of about ¾", thus presenting a smooth surface for the passage of air, and tending to stiffen the wall considerably.

Powder Magazines

As the regulation and inspection of powder magazines is likely to become compulsory throughout Canada, a discussion of this type of building might be of interest at this time. In the main, the desired features to be incorporated in a magazine are, that it be burglar-proof, fireproof, well ventilated, simple in construction and that it afford an easy means of handling stocks.

Here again concrete gives us an excellent medium. It has strength above other building materials, it lends itself to simplicity of design, and a concrete building can under similar conditions be kept cleaner than others, and is resistant to fire.

Col. Ogilvie of the explosives department of the Dominion Government issues a plan of a building which they consider satisfactory, and which, I believe, they intend to adopt for their own use. The principles of construction of this building are shown in the following sketches. (Fig. 2). Concrete is used throughout. Plain walls, 12" thick at the base tapering to 8" at the top, rest on footings sent down to a good bearing. The roof is 6" thick, re-inforced with ½" round bars spaced 6" centres and curved as shown. Double elbow galvanized ventilators, 3" square, with gauze inside are placed near the floor and roof. A floor slab 6" thick is laid over footings and on a well tamped rock back-fill, and graded to the front of the building. A partition wall to form a vestibule for clothes, brooms, etc., is placed at a convenient distance from the front wall, which contains the only entrance and is fitted with a bullet-proof boiler plate door.

It is prohibited to store detonators in a building used as a powder magazine; but this ruling is subject to slight modification. In the magazine shown, an old safe embedded in a mass of concrete at one side of the anteroom making what is virtually a separate building, and utilizing some waste space, is used for the purpose.

All interior surfaces are washed with two coats of cement wash to provide smooth surfaces against the accumulation of dust. All bolts have round heads, nuts being placed on the inside. Figure 2 gives the plan and dimensions of a building to hold about 10 tons of powder

Bath Houses

The provincial mining laws require that at mines where a certain number of men are employed below ground, provision shall be made for them to bathe and change their clothing. The bathing facilities and the general layout of bath houses are largely affected by local conditions and the likes and dislikes of the men in the places where they are situated. Some men prefer showers, others tubs. It will be seen therefore that

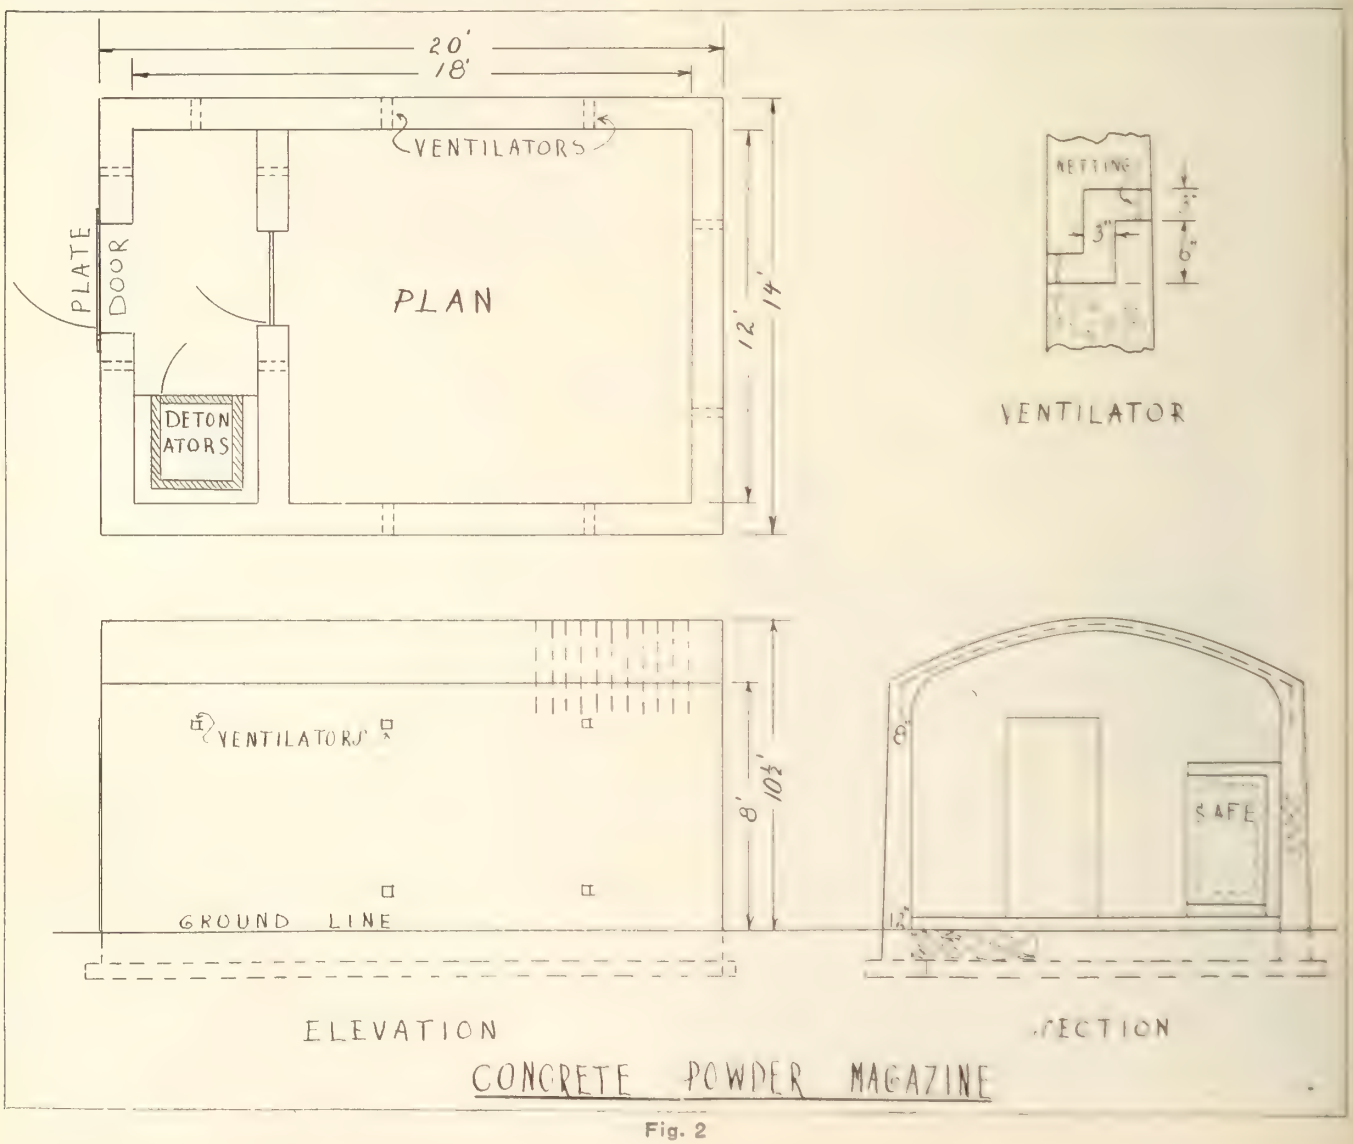


Fig. 2

his building, unlike most designed for some particular urpose, should be constructed to suit the requirements a particular lot of men.

Nearly all the employees of a mine use the bath-ouse, whether working below or above ground; but echanics as a rule do not require to perform com-ete ablutions each day, and basins for a partial wash-p should be supplied. The men of some localities ight prefer to have the usual steel lockers, while hers desire the more modern method of suspending the men while changing. Large ventilators are placed in the roof, and to assist this ventilation the windows are made to open from the inside.

As mentioned before, whether floor lockers or suspended hooks are used, the design is not materially affected; but in this case bottomless lockers or containers at the ceiling are used, into which clothes are hoisted when not in use.

Lamp Houses

While it may not appear at first thought that the requirements of a lamp house are exacting, there are certain conditions that have to be met if the building is to function properly. On account of the gasoline and other oils used in safety lamps, the building and interior fixtures should be of fireproof construction. Not only this, but the exterior walls should be so arranged that, should a fire start inside, it can be isolated as much as possible. This can be attained by having the floor,

Concrete Powder Magazine

he clothes near the ceiling on hooks, which in turn are laced within individual, bottomless containers. The system adopted, however, does not change the design of the building much, the walls being higher where clothes are hung at the ceiling. The requirements for all are the same: it should be laid out so that it can be cleaned thoroughly each day, and it should afford ample space for the required number of men to wash and change without confusion. What is probably of prime importance to the owner is that it should be built of materials that will be impervious for a long time to the effects of large volumes of hot, soapy water with its consequent steam, and that its floors be so built and drainage laid out and maintained so that this water can be removed from the building quickly and efficiently, and not escape through floors and walls to create a nuisance and so hasten the decay of the building. Another requirement from the same standpoint is that it should be made as attractive to the necessities of the different users as possible, so that all will use it, thereby making it not only a utility but a successful financial investment as well.

Fig. 3 gives the general layout of a concrete wash house, designed for both showers and basins. A lean-to on each side of the main or changing room furnishes a shower room on the one hand, a wash-up room on the other. These lean-to's are separately ventilated and heated, and having a wall interposing between them and the main building insures that men changing are not splashed by the showers. The concrete floors and walls permit of easy cleansing by simply flushing with a hose. Walls are also kept painted white, thus assisting in cleaning and lighting. Floor drains at the sides carry waste water to drains laid in a suitable position under the floors. Toilets are furnished with floor type closets, to facilitate cleaning, and the vestibule has automatically closing doors to prevent draughts playing on

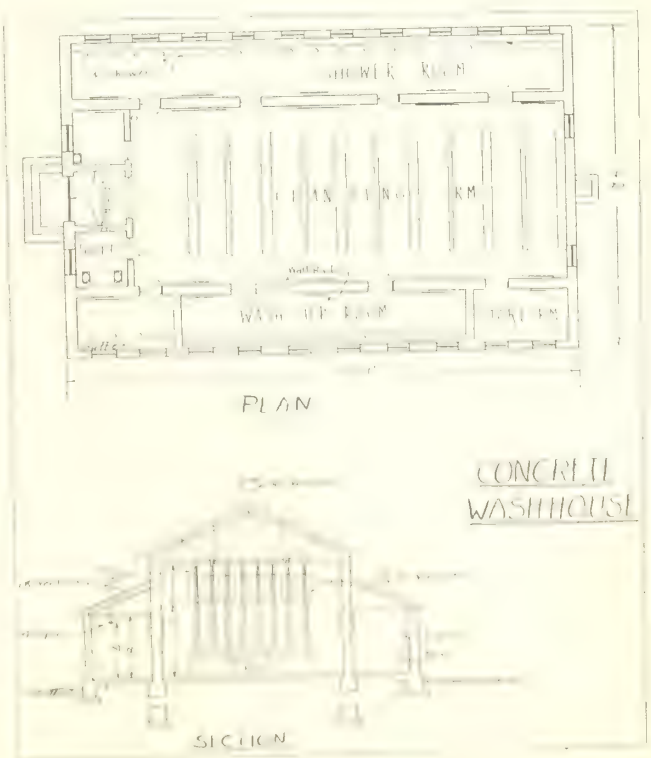

Fig. 3

walls and roof all of concrete, with the windows and door fitted on the outside with light steel or iron shutters that which can be closed when necessary.

There are periods of intense activity in the operation of a lamp house, as when lamps have to be given out to all the outgoing shift of workmen, and received and examined from the incoming shift, all within a period of 30 minutes or less. Usually each workman is allotted a lamp which he uses every day, and this lamp must be found easily and quickly, which necessitates a convenient interior arrangement. Cleanliness, too, is important, to promote efficiency and to prevent fire hazard.

A lamp house is usually small and of simple design, and concrete is particularly suitable for its construction, owing to its fire resisting properties, and the ease of erection where a simple design is adopted.

For the safety lamps, steel revolving drums placed vertically, with numbered niches, each drum to hold 100 lamps, can be placed at a wall in a convenient position to give out the lamps as the workman calls the number at the wicket.

For the electric lamps, charging racks, placed at about 48″ centres and carried out from the wall about five feet, give a convenient arrangement. The charging rack is also numbered with the number of the battery it holds, the cord and headpiece being attached on a hook immediately below.

NEW TYPE OF INGERSOLL-RAND DRILL CUTS MINE AND QUARRY COSTS

For several years there have been few improvements in the method of putting down deep holes in quarrying except the gradual substitution of compressed air power for steam in driving the reciprocating piston drill and the gradually increasing use of hammer drills. There has recently been developed for this class of work and for heavy drifting and tunnelling jobs, a very powerful hammer drill, which has established a remarkable record wherever it has been introduced. Results show that on quarry work alone it has equalled the daily footage of at least two large piston drills. This accomplishment has created a new era in quarrying because it has increased production and lowered costs.

The drill responsible for this radical advance is known as the Ingersoll-Rand X-70 Leyner Ingersoll-Drifter. It appeals particularly to quarry men, because in many rock formations it can be operated satisfactorily without water. This is sometimes an important consideration, especially in cold climates where pipe lines freeze in the winter. On the other hand, where conditions warrant it, water can be utilized.

The simplicity and ease of operation of this new drill wins favor with the drill runner and its rugged construction with consequent negligible upkeep cost and ability to stay on the job, are important features that carry weight with the men who pay the bills.

Designed with ample hole cleaning capacity, it eliminates the time consumed by the use of the separate blow pipe. For the shallower holes, a push button blower device is provided which is conveniently located and easy to operate. For cleaning holes 20 ft. to 30 ft. deep during dry drilling, a special feature makes it possible to draw air from the air chest and to send it continually down to the bottom of the hole, thus effectually removing the cuttings.

An extremely powerful "Sergeant" rifle bar rotation reduces to a minimum the tendency of the drill steel to stick by reason of any faults or seams in the rock; in fact, actual experience has proved that this new drill bottoms the steel to the last inch.

This drill has been employed in mines and quarries with equally good results. At a New England trap-rock quarry, one X-70 replaced four 3⅝ inch piston drills. At another quarry, also in New England, an X-70 does more than the three 3¼ piston drills formerly used. A third New England quarry reports that one X-70 does the work of three 3⅝ inch piston drills. At an Eastern quarry one X-70 is averaging about 180 ft. per day, and at another limestone quarry in the South, one X-70 machine is doing the work formerly accomplished by three 3 inch piston drills. There are now five of these new drills in this quarry. This drill has also proved very successful for drilling and broaching granite. These machines have also recently been installed at various Canadian mines and quarries and their records are readily obtainable by those interested.

Its field is not restricted, however, to quarrying alone.

Ingersoll-Rand X-70 Drifter on open-cut work. Note long steel at the right

It is being used extensively in mining and tunnelling where large, hard rock headings require cut and lifter holes of over 12 ft. in depth. It has also proved very successful where difficult rotation problems are encountered.

There are quite a number of these drills now being used in Canada and other parts of the Empire. In a mine in Newfoundland this new machine recently accounted for 245 ft. of hole in six hours. An average footage of five other different drills in use at this mine on the same day was 137 ft.

The X-70 Leyner-Ingersoll-Drifter is made by the Canadian Ingersoll-Rand Company, 260 St. James St., Montreal, who will gladly furnish additional information to any reader interested in machinery of this type.

CARBON BLACK PLANT

The Sarnia Oil and Gas Company have obtained permission from the Commissioner of Natural Gas for Ontario to erect a plant for the manufacture of carbon black at their wells near Sarnia. This will be the first attempt to make carbon black in the British Empire.

A NEW FERTILIZER

An English inventor, E. Lloyd Pease, of Darlington, has worked out on a small commercial scale a method of making a mixed fertilizer containing nitrogen, phosphates and potash. The nitrogen and phosphorus compound is obtained by using crude phosphoric acid in gasworks scrubbers instead of sulphuric acid. To this is added potassium sulphate obtained separately, and the mixture is absorbed in a suitable carrier. If peat is used to absorb the fertilizer, a substance somewhat like barnyard manure results. No definite figures of cost are available as yet.

The Quebec Asbestos Industry

III — The Recovery of Fibre at Present Lost in the Milling of Asbestos

By G. ERNEST BOOKER

(concluded from page 589)

Having considered briefly the use of a dust chamber as a means of fibre recovery in its simplest form, it is advisable to look into the other methods by which similar results may be obtained. The process of electrical precipitation is one that, up to the present, has not been utilized in the asbestos industry on a commercial scale. Its merits warrant serious consideration.

Development of Electrical Precipitation

The idea of electrical precipitation is by no means new although it is only since 1906 that it has been brought to the aid of industrial activities. As far as is known, the original discovery was made by Hohlfeld in 1824, who discovered that if smoke were passed through an electrical field, the solid matter suspended in it was deposited and the gases became clear. Twenty-five years later Guitard brought the discovery to the attention of the public again, but the matter was apparently forgotten until Sir Oliver Lodge brought the subject up again in 1884. His experiments were the basis of the first British patents, but even these were neglected for another twenty years. Since 1906, however, much more has been learned and the results of the work of Dr. F. G. Cottrell and Sir Oliver Lodge are such that today the process of electrical precipitation is employed in an extensive way in many industries where dust is held in suspension by gases or air.

The Western Precipitation Co., who control the patent rights in Canada, have already done considerable experimental work in the precipitation of asbestos fibre and are confident that a recovery of 90 per cent may be obtained by this process.

Electrical Precipitation for Asbestos Mills

The basic principle of the process is absolutely independent of gravity and consists in the attraction of electrically charged bodies for one another. Thus a particle of matter, if electrically charged, will even oppose gravity and travel upward; but this is not desirable, and so generally a middle course is chosen.

The dust and fibre-laden air is led from the mill as in the previous case and enters the precipitation plant (see Fig.) the velocity of the air being reduced to a certain extent as before. The air, moving at a velocity of say 250 feet per minute, then passes through an electrical field, created by a high potential, unidirectional electric current, the electric current flowing through the dust-laden air between two electrodes oppositely charged. Each and every particle of solid matter suspended in the air becomes charged in this field and is driven by the force of the charge to one electrode and is deposited thereon, the clean air passing on, unaffected, to the atmosphere.

The fibre and dust thus deposited on the electrodes is released from them by vibrations set up in the electrode by a rapping device provided for this purpose. The fibre falls into the hopper, from where it is carried by means of a screw conveyor back to the mill to be cleaned, graded, and packed for shipment as before.

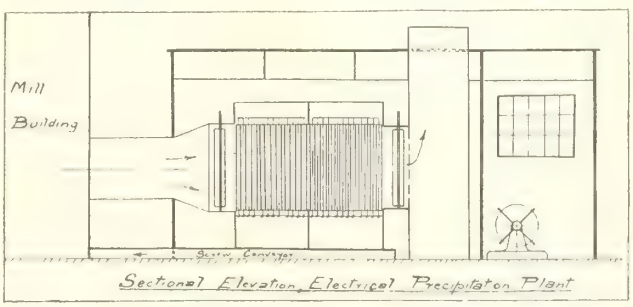
Cost of Installation

The entire equipment is housed in one building and may, if desired, be placed in the mill building itself; but in view of the fact that the space available in existing mills is very limited, the installation of the plant as near as possible to the mill in a separate building is about the best location. The electrical apparatus required for such an installation would include a mechanical high tension rectifier and the necessary step-up transformers and switchgear, all of which is housed in a separate room, but in the same building as the precipitator.

The cost of construction and installation of a Cottrell Precipitation plant capable of handling 50,000 cubic feet of air per minute, including the building and conveyor, is approximately $35,000. But even this considerable expenditure would be rapidly wiped off by the revenue obtained from the fibre recovered. Thus at an efficiency of 90 per cent and taking the same conditions as before, one would obtain 9 tons of fibre per day, which even assuming as low a value as $10.00 per ton, would yield $90.00 per day or $27,000.00 per year of 300 working days. Of course the cost of electrical energy to operate, and the cost of the final cleaning and grading of the fibre must be deducted; but even these items do not amount to much when the increased revenue is compared with them.

Possible Additional Uses

The Cottrell process of Electrical Precipitation has a place of importance in the asbestos industry that is not



realized at the present time; and while it is impossible to foresee the extent of future developments it would appear quite feasible to design and operate the precipitation plant in such a way as to separate the fibre into its various lengths and grades as well as to free it entirely from dust, without any subsequent cleaning or grading being necessary.

To obtain these results in a single electro-static precipitator would overcome not only the waste problem as it is today, but also would simplify the process of milling considerably by eliminating much of the machinery at present necessary to carry out these essential operations.

Mechanical Separation

However, it is not the intention of this article to go into the possibilities of the future in connection with milling, but merely to outline briefly the ways and means by which the present loss in fibre may be eliminated; so we shall pass on to the methods that may be employed under the heading of mechanical separation. In order to make this as clear as possible it is as well to give a definition of mechanical separation as the writer sees it.

The mechanical separation of suspended particles of solid matter from the air is their recovery by a mechanical device or devices, by virtue of which either potential or kinetic energy may be given thereto or absorbed therefrom. This is possibly a rather ambiguous definition,

but the field it has to cover is so extensive that the definition must be equally broad.

As a means of recovering fibre, the various available ways under the heading of mechanical separation should be a matter for serious consideration and research; for by such work of investigation only can the most profitable process be arrived at. Already there are highly efficient forms of equipment in use in other industries which might be suitable for the problem in hand.

Centrifugal Separator

The Centrifugal Separator is such a device. This is in general use and is covered by the above definition of mechanical separation, at it utilizes the kinetic energy available in the dust-laden air. It is probably the simplest form of separator known. The linear velocity of the air is changed into angular velocity, which by virtue of its circular path about a fixed point exerts a centrifugal force upon the suspended particles which overcomes their suspension in the air, and results in the separation of the dust and fibre from the air. The dust and fibre are then collected and returned to the mill for further treatment. The average efficiency of this simple separator may be up to 90 per cent. It is the device at present in use in the asbestos mills for the separation of the regular grades of fibre collected from the shaking screens, and its perfection and further application deserve serious study.

Other forms of mechanical separators employing various devices to trap the solid matter and allow the clean air to pass out can be employed to achieve the desired results and efficiency. Some with screening effects, others which by means of baffles reduce the velocity of the air and secure a gravitational separation, all deserve serious consideration.

In conclusion, then, one may state definitely that the present losses of fibre can be remedied fairly simply, and that the recovery of fibre can be more efficiently carried out than at present, with profit both to the individual mills and to the whole of the Asbestos Industry of Quebec.

MAYO TO BE IMPORTANT SILVER-LEAD CAMP

Natural Resources, the official monthly publication of the Department of the Interior, Ottawa, has this to say in its current issue:

During the past winter there have been hauled from the several mines of the Mayo district to the town of Mayo, on the Stewart river, for shipment after the opening of navigation, between eight and nine thousand tons of ore, which it is expected will average about two hundred ounces of silver to the ton in addition to large quantities of lead

The largest shipments of ore were made by the Keno Hill, Limited, the first company to commence extensive operations in this district. This is the third year of their operations and each summer the amount of ore shipped has exceeded the previous year's shipments. Last winter another company, known as the Yukon Treadwell Company, Limited, developed their properties extensively, and the quantity of ore delivered at Mayo for shipment was almost as great as that of the pioneer corporation.

In addition to the mining companies, a number of individuals are slowly developing their properties, and some of them have obtained ore containing values which will permit of shipments being made.

The ore is hauled on sleighs a distance of about forty-five miles. There was used during the past winter for the first time in this district a "caterpillar" tractor, which was found to be very satisfactory. The intention is to utilize additional tractors next winter, and it is estimated that the output will be doubled and about twenty thousand tons of ore will be available for shipment during the summer of 1924.

The United States Government railway extending from Seward on the Alaskan coast to Nenana, Alaska, is now in operation. The ore from the Mayo district, instead of being towed on scows to the mouth of the Yukon river and there shipped to smelters, will be carried down the Yukon river to the mouth of the Tanana river and up that stream to Nenana, where it will be transferred to the railway and thence carried to the Pacific coast. This means a reduction in the distance from the mines to the smelter of approximately one thousand miles. With the aid of tractors for hauling the ore from the mines to the head of navigation, and by using the railroad from Nenana, Alaska, to the Pacific coast, the cost of transportation of the ore will be considerably reduced and will enable a lower grade of ore to be mined and shipped.

Further prospecting on lands not far distant from Keno hills, where the principal mines now being developed are situated, indicates that the areas from which shipments of ore can be made are of considerable extent, and in some instances evidences of large deposits of low-grade ore have been discovered.

All who are interested in this wonderfully rich mining field and who have watched the development of it since 1918 are, as a result of the work of last year, optimistic, and they feel assured that a permanent mining industry will be established that will rank as one of the great mining fields of the Dominion.

NATIONAL MINING CORPORATION AND COMSTOCK

The National Mining Corporation, of London, has decided to call up the unpaid portion of its subscribed capital, amounting to 4 shillings per 8-shilling share. Official reports to shareholders state confidently that very large profits are in sight as a result of the recent investment in the shares of Comstock Merger Mines, formed to re-open old mines on the famous Comstock Lode in Nevada.

GARNET MINING

The mining and milling of garnet by the North River Garnet Company in Warren county, New York State, is described in the *Compressed Air Magazine* for August. The quarry and mill there have been in operation continuously since 1905, previous operations dating back to 1893. The annual consumption of garnet in the United States is about 6,500 tons, of which 6,000 tons is used to make garnet paper and cloth and the remainder as loose sand for polishing and grinding. The rock, garnet gneiss, contains from 8 to 10 per cent. of garnet. Though the difference in specific gravity between the garnet and hornblende in the rock is only three-tenths of a point, a clean separation is effected by means of "vanning jigs" of unique construction.

RECORD ANTHRACITE OUTPUT

The total production of anthracite during the first six months of 1923 was 59,489,439 net tons, and exceeded the output for any corresponding period. It was 11 per cent. greater than the average for the first seven months of the years 1914 to 1921.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

Night Hawk. — A statement has been issued by the Night Hawk Peninsular Mines Limited, in which it is stated that practically all of the equipment for the 200-ton mill has been purchased and is being delivered. Rapid progress will be made with construction and it is hoped to start the mill the first of November. The company also proposes to sink a new three-compartment shaft to a depth of 425 feet, which will be completed by next January. Underground developments on the 3rd and 4th levels continue to be satisfactory. On the 300-foot level No. 4 vein has been driven on for 400 feet, with the face still in ore. The average grade is $11.50 over a width of 8 feet. On the 425-foot level driving on the No. 5 vein has shown an average grade of $8.00 over 7 feet, and the No. 4 vein has just been intercepted on this level, where it shows $13.50 across 17 feet. Additional camps and buildings are being erected to take care of the additional men required when the mill begins operations.

Porcupine. — Vipond is making good progress with the overhauling of its mill, and it is hoped to have it in shape to turn over ahead of time. It was originally announced that operations would commence in December, but it is now hoped to begin in October.

During the month of July the output of the Dome amounted to $425,547, which constitutes a new high production record in the history of the mine and exceeds by approximately $4,000 the highest previous month's production.

The Conciliation Board, appointed to investigate the demands of the miners in Porcupine for an increase of twenty cents a hour in wages, reports that it has been unable to come to any decision. It recommends that the matter be referred back to a conference between the miners and employers. This is rather an unusual condition to arise, and probably results from the fact that the miners did not simply ask for an increase in wages, but asked for the Board on the specific demand for an increase of twenty cents an hour, and this, of course, was something that could not possibly be considered by the companies. So far as can be learned nothing has been done regarding any further conferences between the miners and the managers.

The "Blue Sky" Law. — The late Drury Government passed what is popularly known as a "Blue Sky" Law, but did not bring it into immediate effect, so far as it concerns mining stocks. At that time it was announced that if it was considered advisable to bring the Act into effect it would be proclaimed on September 1st by the Lieut. Governor. The present Government has decided not to have the law proclaimed, as it is believed that it would have the effect of giving Government sanction to speculative securities, and that it would retard the development of the natural resources of the Province. When the Act was up for discussion members of the present Government were opposed to it, with the result that it will not now become effective.

Iron Ore Committee's Report. — The report of the special committee appointed to investigate the iron mining industry of Ontario has been forwarded to the Government. The report recommends that in order to encourage the development of the industry a bonus of 1 cent per unit of iron in each long ton of merchantable iron ore, natural or beneficiated, and produced and actually marketed from Ontario deposits, be given. It also recommends that the bounty be paid during a period of ten years, and that half the amount be paid by the Dominion Government. It is pointed out that the Province has a steel industry that is a credit to the country, but that it is entirely dependent on foreign sources of raw material and that this foreign supply is within measurable distance of extinction. This country has very large known and undeveloped resources of iron ore, but at the present time not a pound of ore is being produced in Ontario, or, as a matter of fact, in Canada. Sufficient work has been done to demonstrate that Ontario ores, which consist largely of magnetites which need to be concentrated and sintered, are capable of producing high-grade furnace material, and it is believed that a market can be found for approximately 750,000 tons a year. It is also pointed out that within ten years the industry should be self-supporting, and that the development of this industry, in addition to filling our requirements for an important raw material, would be of great benefit to the Province and would provide much needed revenues for the Railways.

Power for the Gold and Silver Mines. — A recent report by the Ontario Department of Mines on the power developed for gold and silver mines, shows a total of 64,490 h.p. turbine capacity connected to generators. This is distributed among the following companies:

Northern Ontario Light & Power Company	30,140
Northern Canada Power Company	28,000
Great Northern Power Company	4,500
Gowganda Power Company	800
Canadian Associated Goldfields	800
South Bay Power Company	250

In addition to the power developed for the mines, about 54,000 h.p. has been installed by the pulp and paper companies. This amount will be very largely increased in the immediate future, as the Northern Canada Power Company, through its subsidiary, is developing 20,000 h.p. on the Quinze River, and the Hollinger Mine proposes to develop another 20,000 h.p. on the Abitibi River. The capacity of the different electrical stations of the Northern Ontario Light & Power Company is 14,300 k.v.a. and the average load is 9,500 k.v.a. Of this amount Cobalt and South Lorrain mines take 4,550, Kirkland Lake camp 1,750, Pulp mill at Haileybury 2,300, and air compressor station and domestic uses 900.

Cobalt. — During the month of July Nipissing produced 298,000 ounces of silver, which is the record monthly production for the present year. This production has an estimated net value of $168,200, and there was shipped from the refinery bullion with an estimated net value of $159,500.

American tourists have the reputation of being inveterate collectors of souvenirs, and this sometimes

results in embarrassing situations. Last week a party of Philadelphia schoolma'ms were visiting the Nipissing Refinery, and after they had left it was found that a number of sample bars of bullion had disappeared with them. These were finally returned, but only after a good deal of trouble and after the special train, which they occupied, had been held up for some time.

South Lorrain. — Directors of the Keeley have declared a half-yearly dividend of 8 per cent., payable September 15th to shareholders of record September 1st.

NOVA SCOTIA

Canon Scott's Visit to Sydney. — Canon Scott arrived in Sydney in humorous vein and informed the reporters his purpose was to study "clam culture." He will, however, proceed with an investigation into the conditions at the Sydney steel plant and at the collieries. True to the marching orders he received when starting out in his profession, he is trying to be wise as the serpent; but whether he will be harmless as a dove remains to be seen. He has made arrangements to inspect thoroughly the steel works and the collieries. Desiring to travel alone, unaccompanied by any person, he found that this would not be possible, even if it were permitted in a steel plant and a coal mine. His intention is to get to the farthest reaches of the oldest coal mine on the island. What he expects to accomplish by this experience it is hard to understand, as coal mines differ according to the thickness of the seam being worked, more than the length of time they have been in operation.

Good Working Conditions in Sydney Mines. — If in the inside workings of the mine Canon Scott expects to find high temperatures and bad conditions, he will be very much surprised, and it may be agreeably disappointed. The Cape Breton collieries are nearly all well ventilated, and as permitted explosives only are used, the mine atmosphere is free from smoke. There is little heat and the places are more comfortable than any city or town on the American continent in the heat of summer or in the dead of winter. The temperature at the pit bottom varies from 55 to 70 degrees in the intake and return airways. The higher temperature registers the air currents as they leave the mine laden with gas and dust, the removal of which keeps the inside sections cool and in a sanitary condition.

The old,disused workings are not open to inspection by anyone,not even a Canon, for nature's forces see to it that all empty spaces in a mine are quickly and completely filled up.

Miners' Houses. — Of the miners' houses we have this to say, from a extensive knowledge of such houses in Canada, the United States and Great Britain; they compare favorably with most in these countries, except perhaps the newer houses at the collieries lately opened up in Britain. We understand that it is Canon Scott's intention to make a full investigation into the housing conditions and we believe that every facility wil be accorded him by the Company to do so Indeed, we are inclined to believe that they welcome an investigation from such a source.

The Reverend gentleman is quoted as stating that the relationship between Capital and Labor should be such that both would get very close together. There are few in Cape Breton who will differ from this sentiment, except where there is no sweet reasonableness on the part of the working men, whose open and avowed purpose was to wreck industry. It is difficult to see how this happy ideal could be realized in the face of the attacks made by labor leaders during the past three years. Now there is some hope.

The Labrador Fiasco. — A number of gold prospectors who went to Stag Bay, Labrador, have returned after a fruitless search for gold. Some of the old timers are very out-spoken as to the gold bearing rocks of the country, or rather the lack of them. A little gold was found by panning in the river, but as one grizzly prospector put it, "There was not enough to crown a tooth". Evidently most of those who went on this barren expedition are disgusted and feel that they have been mislead. *The Canadian Mining Journal* during the winter took special pains to point out that there was not enough knowledge of the district to warrant any expenditure or any large rush of men equipped for gold mining. Everything that was known geologically about the district was published to warn the public against luring advertisements. While there was little to be said in favor of prospecting for gold at Stag Bay, yet we learn that many who occupy the seats of the mighty and whose voices are heard in the councils of the nation were beguiled by the wiles of the stock manipulators and their wild-cat schemes. The Labrador bubble has burst and there are a few more men wiser, though poorer.

Advertisements other than "Employment Wanted" or "Employees Wanted" will be inserted in this department at the rate of 20 cents per agate line (14 agate lines make one inch). $2.80 per inch, each insertion, payable in advance. Space measured from rule to rule. When four or more consecutive insertions of the same advertisement are ordered a discount of 25 per cent. will be allowed.

Advertisements of "Wanted Employment" or "Wanted Employees" will be inserted at the rate of two cents a word, net. Cash must accompany order. If box number is used, enclose ten cents extra for postage in forwarding replies. Minimum charge 50 cents.

FOR SALE. — Troemner Assay Balance in perfect condition. Size 7¾" x 8" x 3½". Sensitiveness .0001 grams. Full set of weights up to one gram. Walnut case with carrying strap. No reasonable offer refused. Apply Canadian Mining Journal, 263 Adelaide Street West, Toronto.

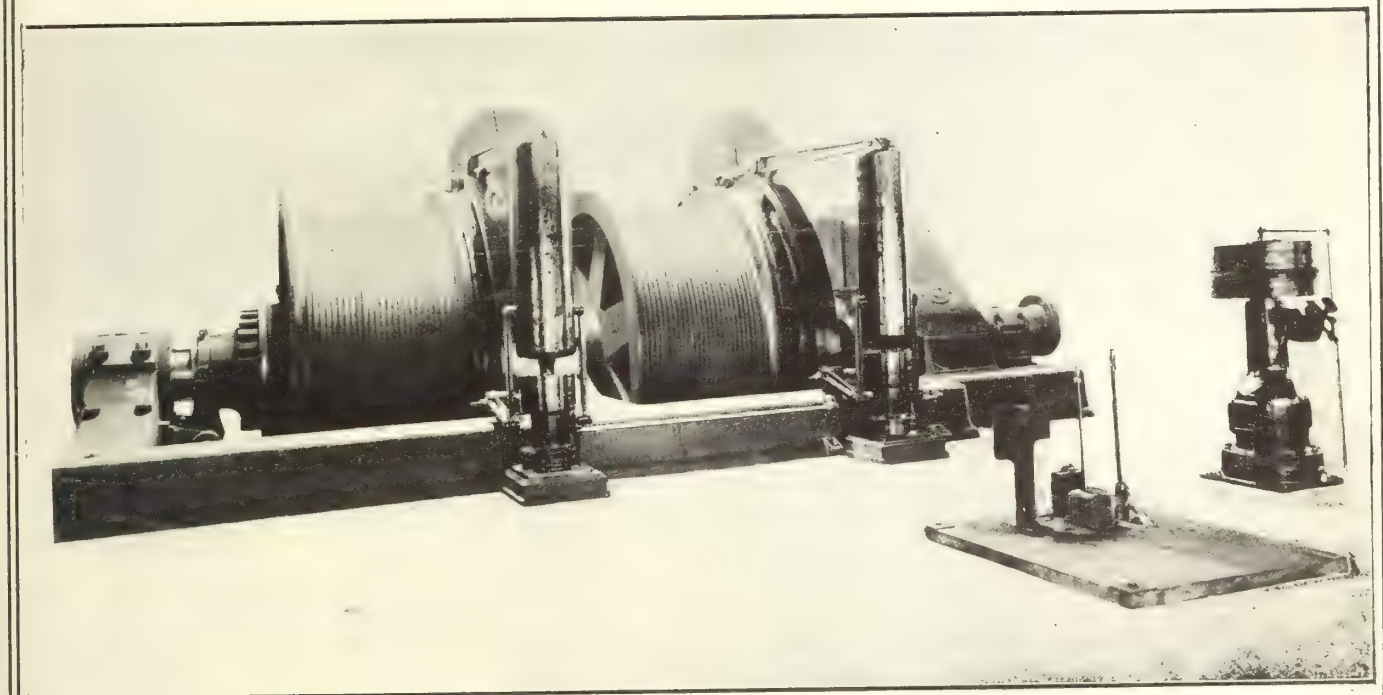
"Ottumwa" Hoists
Built in Canada



This Hoist hauls a 15 Ton Load on a 45° Slope at 1600 ft. per minute. Drums 107" Dia. by 50" face. 1¾" Rope. Driven by 900 H.P. Motor Through Single Reduction Herringbone Gears. Clutches and Brakes Oil Operated.

One of several exclusive features of the "OTTUMWA" Hoist is the PROPORTIONAL PRESSURE CONTROL for power operated brakes. Successive positions of the hand levers give definite and increasing increments of braking effect. A simple and reliable device which effectively replaces the usual complicated gear with superior results. Has proved its worth on many installations.

CANADIAN VICKERS, LIMITED

When Time is a Vital Factor

A BROKEN COG in a gear or a crack in the fly-wheel may tie up your plant. Breaks in machinery cause costly delays. Oxy-Acetylene welding and cutting is saving thousands of dollars yearly in effecting quick repairs.

That is when Dominion Service proves up. The purity of Dominion Oxygen and Prest-O-Lite Acetylene, assures the hottest flame and the utmost economy in fuel. The easily-handled cylinders permit the placing of the welding and cutting equipment within working distance of the job, which alone saves valuable time.

Dominion Service is equally good for the small welding and cutting shop, manufacturing plants, and big shipyards or railroads. If you use welding and cutting in your business, or contemplate the use of the oxy-acetylene process, either in production or for general repair work, it will pay you to know about Dominion Service.

Our representative will welcome the opportunity of telling you how Dominion Service will benefit your business.

Little or no modification of present advantages of slushing

Drilling with "Jackhamers" and scraping with "Little Tugger" Hoist (3 man gang)

Loading car with scraper. Showing slide placed on cross timber

Two 1-H "Little Tugger" Hoists slushing. One hoist handles haulage rope; the other, the tail rope

The question has been frequently asked, "What changes must we make in our present system of mining or in our mine layout before we can substitute "Little Tugger" slushing for hand shoveling and loading?"

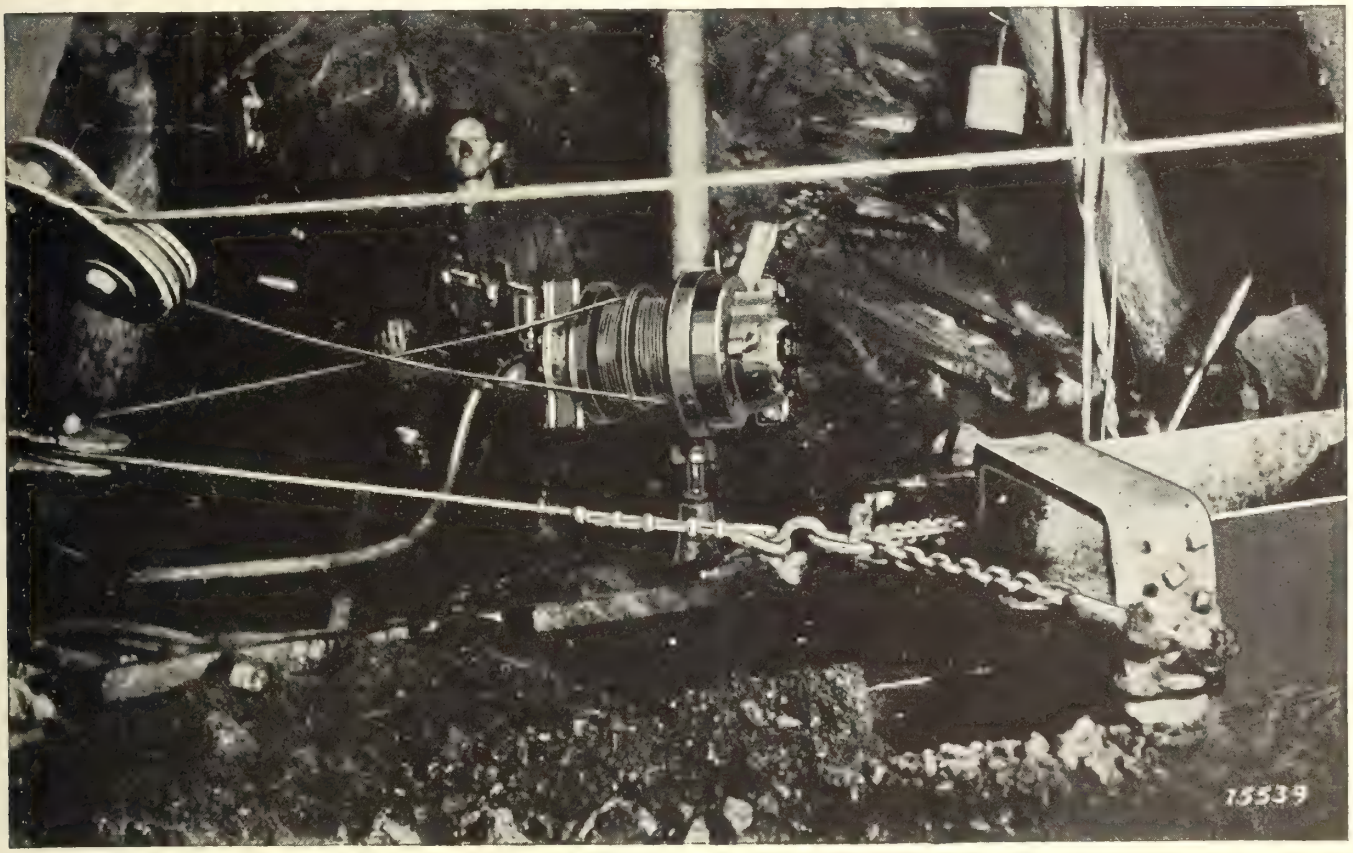
"Little Tugger" slushing has been successfully applied for mucking out drifts, drift stopes and to such systems of mining as top slicing, room and pillar, caving, sub-level caving, etc., without any change in the original layout.

The small size, portability and ease of

Ingerso

Pumps *Air Compressors* *Oil Engines*

mining systems is needed to obtain with "Little Tugger" Hoists



6-H "Little Tugger" Hoist scraping into chute. The hoist has been offset in a niche and the haulage and tail rope are passed through sheaves to get proper direction of haul.

mounting the "Little Tugger" allows it to be moved quickly. As it can be set up almost anywhere (it can be clamped to a column, bolted to a timber, or mounted on a truck in a few minutes' time) it is usually unnecessary to make any rearrangement of chutes, crosscuts or rooms to obtain a very appreciable saving in mucking and loading time and labor.

However, if in planning the layout for a new level, arrangements are made to take greatest advantage of "Little Tugger" slushing. The latter can be counted on to reduce the time to from one-fourth to one-half of that consumed by hand shoveling methods and with a corresponding reduction in labor.

Get in touch with our nearest branch office — there is one near you — for complete information.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387
	Dividends.		

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

C.M.P POWDERED MILK

Keeps Fresh Indefinitely

When the water is removed from milk its souring qualities are suspended—until the powered milk is again mixed with water.

C. M. P. Powdered Milk has the same taste and consistency as fresh cow's milk. Requires only a cool, dry place for storage; bulks small and is easy to transport. Can be used as required—the last tin will be as good as the first.

CANADIAN MILK PRODUCTS LIMITED

347 Adelaide St. West, Toronto

366 St. Paul Street West, Montreal, Que.

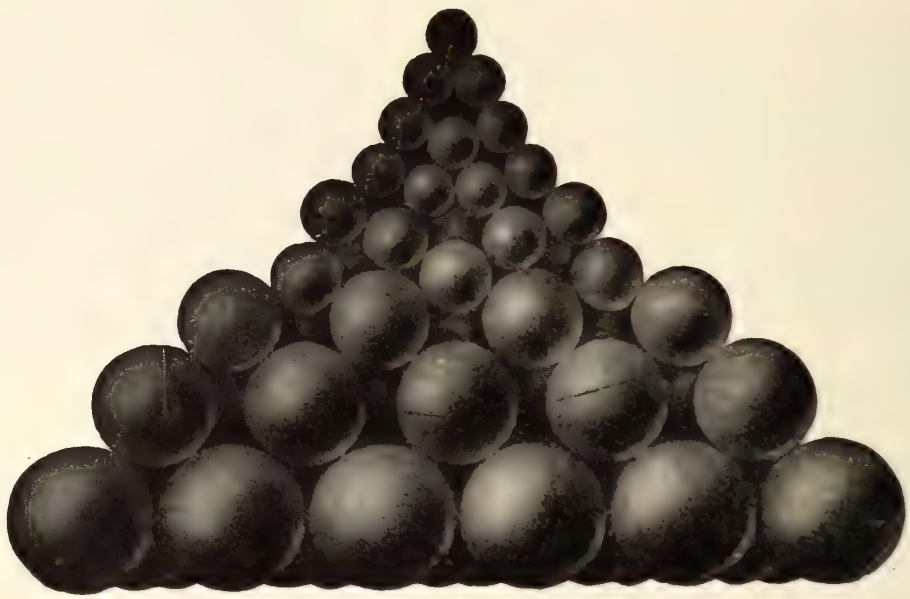
128 Main Street, Winnipeg, Man.

British Columbia Distributors:
Kirkland & Rose, 130 Water Street, Vancouver, B. C.

"TRUMILK"
Full Cream Milk in powder form.
Packed in 45 lb. and 90 lb. drums.

"MILKSTOCK"
Fresh separated Milk in powdered form.
Packed in 50 lb. and 100 lb. drums.

Decrease your grinding costs.



USE HISCO BALLS

"If quality counts use 'Hisco' Products" *Hisco Balls* are noted for superior quality. They are in use in the largest ore and cement mills from Halifax to Vancouver. Forged from Electric Furnace chrome steel, absolutely the best ball on the market.

Sizes 3, 4, 5 and 6 inch carried in stock.
Special sizes from 6 inch up made to order.

A Bank That Is Always Near

The mining engineer — moving as he does from place to place — must needs utilize a bank which has branches conveniently located in mining centres.

The Imperial Bank, with 192 branches throughout Canada and with special concentration in mining districts, offers distinct advantages to those engaged in the mining industry. Patrons of this Bank are never far from their bank accounts, no matter to what part of the Dominion they may go.

Why not ensure adequate banking facilities by depositing your funds with this Bank?

:-: EDITORIAL :-:

IRON AND STEEL PRODUCTION IN THE WEST

A great deal of effort has been exerted by a group of men in British Columbia in an attempt to establish an iron and steel industry on the Pacific Coast. The prime mover in this enterprise is Mr. H. J. Landahl, who has been indefatigable in stirring up interest and has prepared plans for an organization on a large scale.

We understand that the executive of the British Columbia Division of the Canadian Institute of Mining and Metallurgy is watching developments in connection with this proposal. That is as it should be, and it is hoped that in this laudable exercise of its functions the Institute as a whole will avail itself of its opportunity for self-expression. One of its chief claims to existence is that it represents authoritatively the opinion of the Dominion's mining and metallurgical fraternity. Here is a proposal of national importance that requires full public discussion, since public aid has been sought. Numerous members of the Institute are qualified to examine the various phases of the problem and the means proposed by Mr. Landahl to meet the case. Particularly well qualified for such a discussion are those already engaged in the iron and steel business in Ontario and Nova Scotia. Here, then, may lie an opportunity for the Institute to render a distinct and tangible service to our mining industry, by inducing certain of its members to conduct a full and authoritative public discussion of British Columbia's problem.

Meantime we may be permitted to give our opinion on the matter. It appears as though too magnificent and conjectural a superstructure had been built upon foundations that are quite insufficient. There are too many "if's" about the project. We do not say that these queries cannot be answered satisfactorily, but it is the appearance of conjecture, insufficiently supported by fact, that is wrong.

For instance, it is stated that pig-iron can be produced at $20.00 per ton, if coke can be delivered at a cost of $5.00 per ton. Can coke be supplied at this figure? We understand that the estimated cost of local coal operators is nearer $11.00 per ton, and there is still the question of where it is to come from. No coke that would be suitable has yet been produced in British Columbia; but Mr. Landahl hopes to get it from Nicola Valley coal.

Then there is the question of the supply of iron ore. We understand that the main source relied upon by Mr. Landahl is in Mexico, not in British Columbia. Is it reasonable to expect that such ore can be delivered at a rate to compete with the present Canadian and American producers? Reserves of about 30 million tons are cited as being available in British Columbia, notably from the magnetite deposits of Louise Island, Copper River, Porcher Island, Klaanch River and Sechart; but the reports of the provincial Minister of Mines, for which we entertain a whole-hearted respect, certainly do no more than indicate possibilities in connection with these occurrences. There is quite a big "if" here; but it is hoped that the work of Dr. G. A. Young, who is engaged at present in investigating the deposits, will go far towards resolving this hypothesis.

There is also much calculation about the profits to be derived from the manufacture of a multiplicity of steel products. But if the pig iron cannot be produced in the province cheaper than it could be imported, why not talk simply of a steeel manufactory? Could such an industry be established in British Columbia to compete with existing mills that are situated more favorably with regard to markets?

These and other essential points need very careful consideration, the more so in view of the magnitude of the financial proposals. The Imperial, Dominion, and Provincial Governments have been asked to guarantee the bonds of a fifteen million dollar Company, whose common stock would be sold to the public.

It would almost appear that more effort has been expended in the attempt to secure these guarantees than to obtain facts upon which conclusive calculations might be based. However that may be, our own view is that, if the project in its entirety depends upon the proof of these essentials and if such proof may be reasonably demonstrated, it is for individual enterprise to supply this evidence by means of operations on a small scale, to which the multiplication factor could be applied afterwards when the need for it had been shown.

PROFITABLE PROSPECTING

It pays to concentrate.

This is an axiom that applies to prospecting as to other lines of human endeavour. The lesson of intensive prospecting is not easy to learn, but it must be learned if the most is to be made of our mineral areas.

Strange though it may seem, only a comparatively small number of those engaged in prospecting work

are capable of conducting it intensively. The man who travels the water routes and roams through the woods finds it irksome to settle down on five hundred or a thousand acres of promising ground and comb it over until no outcrop remains unexamined. Much more difficult does he find it to confine his attention to a smaller area and trench and cross-trench the overburden in following up a vein or searching for a better one than he has found already. The pertinacity of many true prospectors is tried beyond endurance when it comes to intensive prospecting.

The technically trained mining man's faith and perseverance are, on the other hand, strained and often broken for another reason. By training and experience he has become accustomed to calculating definitely the results he intends to achieve. Day by day he expects to mark his progress towards this end. Even the vicissitudes of underground exploration are relieved by definite progress; the drift advances, round by round, and another shot may put the ore in sight. But exploration on the surface is of necessity more promiscuous and usually has less definite objects. It is a search guided as much by instinct as by reason. It requires a disposition, either natural or acquired, that is not at all common even among mining men, whose professional work is considered by other engineers as "chancey" above all others.

One would have thought that the lesson taught at Cobalt would have been learned once for all. But it is not difficult to persuade one's self that the little prospector's pick or hammer and steel are tools preferable to dull and dreary pick and shovel. Apparently the lesson has to be learned over again in each new mining camp. Of course, when once the camp becomes established, or even when it has drawn the attention of investors who can afford to put on a gang of regular pick-and-shovel men, the problem of intensive prospecting is solved. It is during the period of the original search, while the hope and faith of the prospector are still the mainspring of effort, that the difficulty remains.

Our budget of news today from northwestern Quebec records some instances that confirm our faith in intensive prospecting. A few weeks ago the find at Lake Fortune was made by this means. Last week a new ore zone on the property of Noranda Mines was announced, found in the course of a systematic search on the surface. An adjoining property has been abandoned; we wonder if its surface has been scoured with the same thoroughness with which the original vein was examined. The Stabell property is showing increased and very satisfactory values as a result of diamond-drilling. Will trenching disclose a vein system, as at Hollinger?

Many a mining district has been damned and abandoned for lack of the systematic exploration that commences on the outcrops, progresses through a further stage by the aid of pick and shovel, and is concluded with hammer and steel or the diamond-drill. This fact is filtering slowly through to the consciousness of our mining engineers and mining investors, with the result that these old camps are no longer avoided like plague spots. A large number of them deserve the intensive prospecting we have attempted to discuss above, and none of them have had it. We are confident that when once they become the vogue—an event that is bound to happen—some of these old, disreputable, stock-jobbed, and thoroughly discredited camps will be transformed into new camps that will rank with the best. Then we shall realize more completely than ever that it pays to concentrate.

A BLESSING IN DISGUISE

The anthracite strike that has been threatened so long has come, for how long it is impossible to predict. Its incidence has not, however, caused the consternation that accompanied the strike of last year. Both here and in the United States those accustomed to use anthracite have learned during the past twelve months that there are other domestic fuels available, some of them as good as it, or better, and large amounts of these substitute fuels have been put into the cellars or the dealers sheds.

To those in eastern Canada formerly wholly dependent upon anthracite for a household fuel, the threat of a strike, and now the fulfilment of the threat, is a veritable blessing. If an embargo should be placed upon the export of anthracite to Canada, the blessing may take on a thin disguise, but its real usefulness will be augmented. There are various reasons, which have been set forth in many places during the past twelvemonth, but will bear repetition.

In the first place, we Canadians have now, at last, been at least partly convinced that we should make use of our own fuel resources so far as is economically possible. As a result, coal from Nova Scotia is finding a ready market at St. Lawrence ports, and Manitoba's supply for the year has been drawn mainly from Alberta. Active preparations are under way to provide an additional outlet for these coals as by-product coke for household use, and the carbonizing plant now under construction at Ford, Ontario, may provide for the similar use of non-coking coals. Several thousand tons of Alberta domestic coal are on the way to Ontario under the special $7.00 freight rate, and one operator is reported to have offered his coal in Toronto at $11.50 a ton, including the $9.00 freight charge of Sir Henry Thornton's standing offer.

One opportunity has, so far, escaped us entirely. We have failed to make any progress whatever during the past year in utilizing the vast resources of peat available up and down the eastern provinces. The best efforts of the Joint Peat Committee and their engineer, Mr. E. V. Moore, have apparently been wasted

on us. They have worked out a commercially feasible process for making a good domestic fuel; but our investors are so obsessed by the vision of former failures in the manufacture of peat that they will not put up the money to instal a new commercial plant or to renovate the old one. We hope this strike may induce a change of heart.

The importing of domestic grades of coal from Great Britain has been inaugurated on a moderate scale. As announced last spring by emissaries of British coal operators, screening plants have been provided at the docks and coal of unusually good quality is now available.

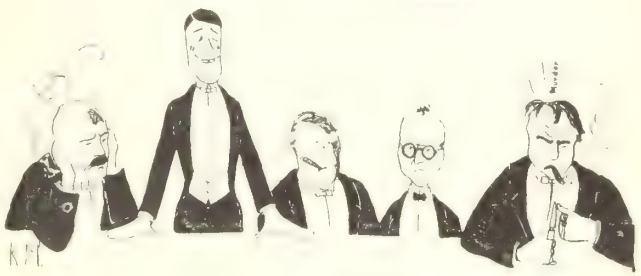
Most important of all, perhaps, is the fact that the threat of a coal famine has induced a large fraction of those dependent on coal for household fuel to fill their bins during the summer months. The constant insistence of the Dominion Fuel Board and the provincial fuel controllers upon this point has had its result, for which they are to be heartily commended. If the habit persists during normal times, it will have a marked effect in giving steady employment to the miners and carriers that provide the fuel, and thereby will make it cheaper.

The experience with new fuels that will be the lot of many Canadians during the coming winter will doubtless open our eyes to one fact that heretofore we have ignored persistently. The anthracite imported from the United States is an inferior fuel, as well as expensive. Its fancied exclusive convenience, too, is an illusion that will be dispelled when once we become accustomed to a really good fuel. Some of the coal now available in Ontario and Quebec from Great Britain and Alberta has twenty per cent. less ash than Pennsylvania anthracite, has a higher calorific value, and costs less, though it is worth more.

Yes — in the long run these anthracite strikes will prove to be an educative influence that will offset much temporary discomfort and dislocation of trade and of personal habits.

A press despatch from Washington states that the Bureau of Mines has announced the successful conclusion of tests with the new type of carbonizer being tried out jointly by American and Canadian technical authorities. Our readers will recollect that the experiments of the Lignite Utilization Board at Bienfait, Saskatchewan, though successful in many particulars, failed through the inadequacy of the essential part, the carbonizer. The simple type now under trial is stated to be thoroughly satisfactory. If extended commercial trials on the lignite at Bienfait should be equally satisfactory, it will open up for general use the most easterly portion of the vast beds of fuel underlying the western plains. The lignite can be mined cheaply by steam-shovel and awaits only a feasible method of driving off the excess of water and combustible gases to make it useful as a fuel of the highest grade. A satisfactory means of briquetting has been evolved already at Bienfait.

It is becoming the vogue for men in high positions to repeat publicly the statement that Canada has vast undiscovered mineral resources. "I believe you have not "even begun to realize the extent of the mineral re- "sources of this country," said Lord Birkenhead, formerly Lord Chancellor in the Lloyd George government, in his address to the Canadian Bar Association in Montreal this week. "I believe the future welfare and "prosperity of this country depend fully as much on "mining as on agriculture, and that is saying a good "deal," said Hon. Chas. Stewart, Minister of Mines at Ottawa, in his address to the American mining engineers last week. So the chorus grows in volume. If we temper our enthusiasm for the mining industry with discretion, this publicity will serve an eminently useful purpose. It is up to us of the mining profession to see that the professional boomsters and financial sharks do not make capital of this enthusiasm.



THE SPEECH

We had stood, without a whimper,
His preliminary simper;
We had smiled a sickly smile at all his jokes;
We had paid polite attention
To each topic he did mention,
While we soothed our weary souls with many smokes.
But we couldn't stand the strain
When he quoted old Mark Twain,—
Hackneyed thing that every novice loves to quote —
And, as always, now and ever,
Blast the bird! He thought it clever,—
Didn't know he made himself a giddy goat!
But if ever once again
Any blighter quotes Mark Twain,
We have made a solemn vow to strike him dead!
And we'll throw him down that shaft
At which other fools have laughed,—
And the bounder's blood will not be on our head!

J. C. M.

PUBLISHERS' ANNOUNCEMENT

The publishers of the *Canadian Mining Journal* have much pleasure in announcing the appointment of Mr. H. G. Nichols as Associate Editor. They have secured his services on behalf of the Canadian mining public particularly with a view to the needs of British Columbia, where Mr. Nichols is conducting his professional work as mining engineer and geologist. They hope by this means to overcome in large part the disability imposed by the twenty-five hundred miles separating the office of publication and the mining districts of British Columbia. The mining industry of Canada, like the Confederation, is one, and through Mr. Nichols' present appointment, the *Canadian Mining Journal*, the mining industry's public representative, hopes to serve it more adequately and more worthily.

MR. H. G. NICHOLS

Mr. Nichols' training and experience make him eminently qualified to represent publicly our mining industry. He is one of the many Associates of the Royal School of Mines whose field of endeavour has become the world at large. His first work after graduating in 1889 was at a gold mine in North Wales; his second, at a coal mine in South Wales. South Africa, and then Swaziland, next claimed his attention. In 1897 he came first to British Columbia, where he had a varied experience in the metal mines. For an interval California, Honduras and London were successively the scene of his labours. In 1907 he returned to British Columbia to direct work at the Ymir Gold Mines, which he managed until operations ceased in 1910.

Metallurgical research next occupied Mr. Nichols in London, whence he returned to South Africa to instal a plant at the Robinson mine. A visit to the placers of the Lena district in Siberia was followed by further research work on Cornish tin ore.

The war found Mr. Nichols with Messrs. Bainbridge, Seymour & Company, whose activities had taken him to Burma, the United States, Spain and other parts of the world. He enlisted and served until demobilized in 1919. After one year in Mexico he returned to British Columbia, where it seems possible his old friends, aided by the natural attractions of the province, may induce him to settle permanently.

In addition to activities of the purely professional variety, Mr. Nichols has occupied himself during the past four years with public questions affecting the mining industry of British Columbia and of the Dominion. He is one of the leading spirits among the Western members of the Canadian Institute of Mining and Metallurgy. The Mining Association of British Columbia also has had the benefit of his vigorous support. Now that the *Canadian Mining Journal* is so fortunate as to claim part of his attention, the Canadian mining public will benefit still further from the sound judgment that has resulted from his world-wide experience and from the clear-sighted idealism that has been his guide through all his travels.

GOLD MINES IN FRANCE

One seldom hears of gold mines in France, yet there are several of them, which are described briefly in the current issue of *Mines, Carrière, Grandes Entreprises*. At Lucette in Mayenne two quartz veins in schist and quartzite of Silurian age contain stibnite, mispickel and gold. At La Belliere in Maine-et-Loire veins of auriferous mispickel occur in pre-Cambrian rocks, and the gold is recovered by amalgamation and cyaniding, and a concentrate is made from which arsenic is recovered. At Le Chatelet auriferous mispickel occurs in quartz associated with pegmatite, yielding both gold and arsenic. There are half a dozen gold mines in addition, most of them discovered and operated during the last two decades. The average gold content of the ore is approximately the same as that in the Transvaal, but all the mines are small.

SYNTHETIC AMMONIUM NITRATE

When Germany was blockaded early in the war and could no longer draw her supply of nitrate from Chile, her chemists at once applied the results of scientific research conducted previously to the establishment of works to make synthetically from air and water the much used explosive, ammonium nitrate. There is now under construction at Billingham on the east coast of England the first British factory for the manufacture of ammonium nitrate by this process. Brunner, Mond & Co. are the builders.

J. C. M. of the C. M. J.

By ALEX. SMART, B.A. (Oxol.), B.Sc., (Bovril)

Some of the great poets have been victims of most extraordinary non-recognition of genius. No less a one than Wordsworth wrote volume after volume of poetry and at first met with ridicule and execration. Have the readers of the C. M. J. been as keenly appreciative of J. C. M.—whoever he may be—as they might? True, no ridicule has been heaped upon him nor has execration been his lot. On the other hand no one has, as yet, seen fit to give his verse the praise it deserves. I thought of doing so myself, but there are those from whom praise is not acceptable, partly because of their inability to judge and partly because of their inability to appreciate and distinguish real worth.

Fearful lest my opinion would not carry sufficient weight and lest my criticism would reveal the student lacking in literary attainments, I submitted J. C. M.'s *pièces de résistance* to world-wide recognized critics. Their very names signify their qualifications and their ability to speak with authority and to voice opinions that readers of the C. M. J. will follow with interest.

I have not hesitated to gather some visions in Paradise. In comparison with the mundane opinions, the work of the great poet J. C. M. may be said to have caused as great a flutter in realms heavenly as in those terrestrial. The comments of the critics are given in their exact words. Here is what they have to say:

JOHN STUART MILL—"I sure do like J. C. M's poetry. Our initials are very similar. His poetry teaches me to increase my interest in the common feelings and the common destiny of human beings. But kiddo, say, these lines sound like Wordsworth's:

'Precocious child! so lavishly endowed
With mental growth to others not allowed!' "

STEPHEN LEACOCK—"J. C. M. (whoever he is) is not destined to become extinct like most poets. Far be it from me to accelerate his extinction. I appreciate the sympathetic yet economic turn in the lines

'My first instinct was to dip
Into my pocket for a tip.'

Editors will readily countenance his poetry."

(Note—It was a mere coincidence that the two great economists were interviewed one after the other.)

WILLIAM WORDSWORTH—"There is something in the madness of J. C. M. that interests me more than the sanity of Lord Byron or Sir Walter Scott. His is the simple product of the eight-hour day. Like myself, J. C. M. is a great poet. I never turned better lines than these:

"Let us with a cheerful mind
Cherish hopes when so inclined:
Disregard the croaking gent
Who insists the world's hell bent.' "

PERCY BYSSHE SHELLEY——" 'Ethereal' best expresses the quality of J. C. M's genius. How I would like to know his name! His poetry is full of dynamic effects. Read, re-read and let me add, read again those dainty lines:

'He wouldn't use crimpers; he used his teeth,
Now the flowers are above and he's underneath.'

His poems are like the waterfalls of Niagara which, tumbling from a height of thousands of feet, are shattered into foam by the air and waved about over the valley. Very beautiful is the descending spray; the rainbow dwells in its bosom; but there is no longer any stream, nothing but an irridescent mist. Wonderful! Wonderful!"

(Note—Mr. Shelley was a trifle out on his measurement of Niagara, but we were glad to have his opinion notwithstanding its length).

LORD MacAULAY—"I abhor *noms de plume*. This J. C. M. has an endless wilderness of twaddle, but he has some fine discriptions. Imagine, though, a poet mistaking a college educated man for a tramp .....Perfectly ridiculous!"

(Note—the essayist-historian was decidedly grouchy when interviewed. However, we can say that his tastes and habits of mind make him a poor judge of a poet such as J. C. M.)

LORD BEAVERBOARD—"In J. C. M. the C. M. J. has a poet whose forcefulness ought to bind the serious and humorous interests of the mining industry. Like my A. B. B., he has a great future before him. To think of a young country producing us three in a generation!—Remarkable! But, why the disguise? Think of all that 'The Gentleman with the Duster' is missing!"

(Note—Another remarkable coincidence that we should interview two noble lords one after the other).

JOHN RUSKIN—"Your J. C. M. displays the majesty of simple feelings. With high reflective truths he analyzes the ways of men. A greater poet than your Robert Service, he reaches the essentials. I like his, 'as if to paint the lily too.' It combines a word and action of my own thoughts."

THOMAS CARLYLE—"I have a real respect for the antique greatness of his devotion to the mining industry. Sometimes I find his saintly reflections—'St. Simeon Sytlites' and possibly 'Didymus and Aquinas'—unfathomable. But, the dignity of labour suffers not—not even in such lines as

'His jaws were working on a chew.' "

SAMUEL JOHNSON—"Some poet, believe me! This J. C. M. abounds with images, which find a mirror in every mining mind, and with sentiments to which every mining bosom returns a echo. Now, J. C. M.'s lines remind me somewhat of that northern savage, Robert Burns, whose 'Cottar's Saturday Night' was good verse for a Scot:

'Your grouch evaporated while you stood
With outstretched hands and eagerly did wait
The heaped-up riches of your breakfast plate.' "

HOMER— (Note—Not the one who smote his blooming lyre to accompany, "Yes, we have no bananas today.")

" 'Tis a wise poet that dodges dactylic hexameter in English, though it is delicious in Greek. I like his 'heartless dawn,' in comparison with my 'rosy-fingered morn.' But, of all his lines, this:

'Lo! at his fire the heaven-sent cook performs,'—

is worthy of a place among the classical gems.

PUBLIUS VERGILIUS MARO — "This person J. C. M. is too modest. Remember you not that some unscrupulous fellow thought it safe to claim my verses as his own? Have this J. C. M.—whoever he may be—write his name in full so that more than the world of letters may have his full name. And then, more's the

honor to him (*laudite jam rivos,* or as your Bliss Carman might say, 'That ought to hold him for a while.' ")

JOHN DRESSER—"While it seems that he 'just can't mention his name,' I, as president of the C. I. M. M. wish to express my appreciation of J. C. M.'s output. Scanning his strikes, sampling his verse along the shear zones, examining his stanzas horizon by horizon, and tracing out every contact, I have concluded that J. C. M's poetry should not be 'just casually meditated' upon but should be given serious consideration—all excepting one poem."

Having interviewed all these famous critics I felt that, as Wordsworth had been frequently consulted about his own poetry and had just as frequently expressed his perfect satisfaction with his own efforts, it would only be fair to the anonymous J. C. M. to interview the great Canadian poet, with the object of obtaining his own opinion of his own verse. I asked for his views in prose, but once again the poet got the better of him and he quoted:

"The moving accident is not my trade,
To freeze the blood I have no ready arts;
'Tis my delight in summer's shade
To pipe a simple song for thinking hearts."

Now I call that modest; but nevertheless, I regret that I am unable to give to the readers of the C. M. J. the great poet's name.

The great ones of all time have appreciated J. C. M., and it is up to us, "the people of distinction in society" (i. e. those connected with the mining industry) to see that the appreciation of J. C. M.'s genius is continued. Let us not forget that his is a poet's pen which

".....gives to airy nothings
A local habitation and a name."

VIVE J. C. M. OF THE C. M. J!

(P. S.—I understand that it is customary when writing articles for technical journals to send a photo to let the reading public know whether the writer is well thatched or bald. The writer is somewhat sensitive of approaching baldness, so refrains.)

LETTERS FROM READERS

The Asbestos Industry of the Province of Quebec

To the Editor,
Canadian Mining Journal.

Sir:—This letter is inspired by, and most emphatically refutes, the two articles by Mr. G. E. Booker, published in the *Canadian Mining Journal* on July 6 and July 20.

The Asbestos Industry of the Province of Quebec is in the best possible hands. The engineers employed, both as consultants and operatives, are of the highest type. Their remuneration probably averages higher than in any other mining camp in the Dominion. They have their reputations to uphold and if they were not considered competent would cease to be employed. Their employers have invested some thirty million dollars in this area. They are careful that this investment is adequately protected by selecting, on the best advice obtainable, thoroughly competent and reliable men to fill Executive, Managerial and Operative posts.

Turning to the earliest records in the writer's possession we find that in 1903 the sales of Mill Fibre exceeded the sales of Crude in both value and tonnage, and undoubtedly this condition existed for several years before this date. The Mill Fibre business has developed greatly in the past 25 years, but it must be realised that this development was keeping pace with the requirements of the manufacturer. No great corresponding increase in the production of Crude was possible. The same rock from which Crude alone was extracted was milled to recover fibre, and it was only milled to the point where it was possible to pay for the cost of milling by the increased value of extracted fibre.

Market conditions govern the percentage of recovery of Fibre in any mill. The Asbestos "dust" which Mr. Booker claims is wasted costs more to produce than it will fetch. The demand for such material is far less than the potential supply, and is judiciously kept level by the Mine Operators, who cannot see the wisdom of selling more material than they can help at prices below cost of production.

Mr. Booker claims that from 25 per cent. to 30 per cent. of the possible extraction is wasted. This statement is probably quite correct. He says, however, that 25 per cent. of the total mill rock yields no return. An error here; he meant, doubtless, that 100 per cent of the mill rock yielded 75 per cent of its fibre content. This 75 per cent return is saleable, and will return a profit. The cost of producing the other 25 per cent. is so high that it is impossible to market it to advantage.

It is quite wrong to assume that the possible production in 1922 and the actual production in the same year varied directly in tons and value. Mr. Booker estimates about 44,000 tons, having a value of about $1,730,000, could have been produced without further cost. As a matter of fact, this 44,000 tons could not be worth more than $8.00 per ton, or $352,000.

Admitting that $352,000 is a considerable amount of money to throw on the dumps, let us realize that against this sum are the costs of the further milling and collecting of this material, the bag cost, bagging cost, loading, teaming, and warehousing, and the overhead expense of the enlargements to storage sheds made necessary by the increased tonnage. Other factors, not quite so noticeable, enter. Extra superintendence is essential; also testing and inspection of shipments would create losses in time and money.

Dust chamber material is saleable in small quantities. It is only saleable when reasonably free from rock and grit. The market is limited and the prices obtained do not warrant its collection, but local legislation compels the mills to collect it. The dust that covers floors, rafters, etc., in the mills themselves contains such a quantity of finely ground rock particles as to be unsaleable.

Undoubtedly reinforced concrete construction is preferable to wood. Unfortunately the existing milling methods have not undergone any sufficiently radical change in the past twenty years to warrant scrapping the present mills, and their replacement with steel and concrete or similar construction. The cost would be so great as to render it impossible for the mine owner to receive sufficiently increased value to cover the interest on the outlay.

It has yet to be proven that any other type of mill will do the work as effectively and cheaply as those now in use. Some of the most rickety, patched-up mills in the district do as good work as the best constructed.

Regarding mill practice, Mr. Booker assumes that two crushings are sufficient. As a matter of fact, less than one-fifth of the tonnage of fibre now produced could be recovered in a lay-out of this type. A secondary crusher cannot be calculated to reduce 4" material to a sand.

The writer knows of no case where the fibre rests periodically in its transit through the mill. It travels at a uniform rate from the mill bin to the bagging pile, stopping there only for inspection and testing.

It is to be regretted that a publication of the standing

of the *Canadian Mining Journal* should see fit to publish a paper containing such hopeless inaccuracies, making charges of inefficiency and waste against men who have devoted years to the establishment of the asbestos industry, particularly when these charges are laid by one who positively cannot have either experience in, or any knowl edge of mining, milling or marketing asbestos. His own words convict him.

Montreal, Que. Samuel Davis.

PERSONAL AND GENERAL

Mr. George L. Burland has returned to the asbestos district of Quebec, to engage in an investigation of a wet method for treating asbestos. During the past three years a considerable amount of research into this treatment in water was conducted at the Vimy Ridge property of the Bennett-Martin company. The work is being con tinued now in Thetford.

Col. John A. McDonald has been appointed superintendent of the electrical department of the steel plant at Sydney, Nova Scotia. He succeeds Mr. C. C. Boucher, who has resigned to accepted a position in Chicago.

Mr. John A. Dresser, President of the Canadian Institute of Mining and Metallurgy, accompanied the excursion of the S. I. M. M. E. throughout the tour of Ontario and Quebec. He fulfilled with his usual grace and vivacity the function of official host on behalf of the Institute.

Canon Scott has returned to Quebec after a two weeks' tour of inspection of the steel plant and collieries at Sydney, Nova Scotia.

Dr. Alan M. Bateman, of Yale and Dr. E. S. Moore, of the University of Toronto, have been recent visitors to the Portland Canal mining district, and it is reported that Dr. Lindgren, of the Massachusetts Institute of Technology, proposes visiting the same camps before the summer season closes.

Dr. Malcolm MacLaren, geologist of London, has been making a study of the mineralization of the Premier Mine and of the general geology of the Portland Canal Mining Division.

Mr. F. S. Lewis, senior partner of the firm, Sidney Lovell & Co., London, accompanied by Mr. H. C. Beaven, who is associated with the same firm, has completed a tour of the newly opened up mining camps in the northwest of British Columbia. They were particularly in terested in learning at first hand the prospects of the M. C. and Prince John Groups of mineral claims, as both these properties have been introduced to the London market.

Dr. Charles Camsell has sailed for England to advise Hon. Charles Stewart, Minister of Mines at Ottawa, on matters pertaining to the mineral industry during the coming Economic Conference.

Mr. M. C. Keith, of New York, accompanied by Mr. H. A. Guess, managing director of the Premier Gold Mining Co., and Mr. H. B. Price, mining engineer, is visiting British Columbia with the purpose of visiting the different mining properties of interest in the northwest. It was suggested that he would pay special attention to the Big Missouri Group in the Portland Canal district, which now is under development by Messrs. Trites, Wood, and Wilson.

Mr. H. S. Denny has passed through Montreal on his way back to London. Mr. R. B. Lamb, who was with him on his recent visit to the Portland Canal district of British Columbia, has returned to the east also.

Dr. Alfred Whitman of the University of California has made an examination of the Castle-Tretheway mine in Gowganda.

Mr. Cyril W. Knight left the employ of the Ontario Department of Mines at the end of last week to join the staff of Nipissing Mines. The first part of his report on the silver areas to be published is the section dealing with South Lorrain. This was issued as Bulletin No. 48, on the occasion of the visit to South Lorrain of the visiting American mining engineers.

Messrs, Fraser D. Reid, J. J. Denny and R. H. Hutchison, of Cobalt, added materially to the facilities of the A. I. M. M. E. excursion also. Their record of the metallurgical practice of the camp, published as Bulletin No. 47, was put in the hands of the excursionists in Toronto.

Colonel Rowland C. Fielding, consulting engineer for the Porcupine-Davidson Gold Mines, is in Northern Ontario on a tour of inspection on behalf of a British syndicate. Col. Fielding is a mining engineer by profession and has had a world-wide mining experience; but he has managed to sandwich in a good deal of military experience. During the recent war he served with distinction in the Coldstream Guards, with which regiment numerous members of his distinguished family have long been associated.

Mr. Robert Wallace, who for thirty years has been connected with the International Nickel Company as metallurgist at Bayonne and Huntington, has retired from active service. He has been to a large extent responsible for the remarkable metallurgical results obtained by the Company, commencing at the time when "nickel" spelt "old Nick" to the copper refiners at Bayonne. He remains with the Company in a consulting and advisory capacity.

MINING STANDARDIZATION

The American Mining Congress will hold a National Standardization Conference, under the auspices of its Standardi ation Division, in Milwaukee on September 26th to 28th. The mechanisms and materials used in mine; and mills, as well as methods used, will be discussed. There will be addresses by prominent speakers; but the principal concern of the meeting will be the discussion of reports on standardization submitted by various sub-committees. The object of this standardization effort is epitomised as "the elimination of waste in the mining industry; the simplifi cation of mining methods, practice and equipment; efficiency in operation."

RADIO EXHIBIT AT CHEMICAL EXPOSITION

How the radio is finding a use for many of the rare metals will be shown at the composite radio exhibit at the Chemical Exposition which opens at the Grand Central Palace, New York, on September 17th. A number of well-known firms have contributed products of their manufacture which deal directly or indirectly with the construction or operation of the radio. Thorium, tellurium, selenium, tantalum, molydenum, — all of these metals rarely getting into commerce on a broad scale, will be demonstrated. In addition to the metals, carborundum crystals, synthetic resins, hard rubber radio parts, extremely fine precision instruments for electrical work and a number of other important features of the radio constructions, will be demonstrated. Alundum tubes for use in measuring high temperatures, particularly in furnaces for drawing tungsten tube wire, will also form part of the exhibit.

The MacKenzie Report on Southern Vancouver Island Coal Reserves

By C. M. CAMPBELL*

It is necessary in the interests of national economy that the amount of coal available for present and future use be ascertained with some precision.—J. D. MacKenzie.

The Geological Survey, on June 1st last, published the report of the late J. D. MacKenzie dealing with the coal resources in the southern part of Vancouver Island. Mr MacKenzie announced his conclusions last fall; his report has now been published for some time; it deals with an extremely important matter, yet it has been ignored not only by the public but also by the technical press.

The industrial supremacy of the countries about the North Atlantic is a large measure due to their possession, at or near tide-water, of large deposits of coal. There are no deposits of coal of real importance along the American North Pacific. Coal is found in Washington State, but it is limited in tonnage and costly to prepare. Coals from the interior are subject to a $4 to $6 per ton freight handicap. In Canada the same is the case in regard to Alberta coal. It would therefore appear that the coal on Vancouver Island, where it outcrops along the protected side of the Island, where climatic conditions are very favorable and where there is a large tributary population, should give that Island a great advantage in industrial matters. Vancouver Island coal has undoubtedly been of great importance to British Columbia in the past and will continue to be of great importance for some time longer. Why it is not likely to be of the supreme importance that previous official articles would indicate, is dealt with in the MacKenzie report.

Former Surveys

It appears that coal was known to the Indians in the early days and that Dr. W. F. Tolmie, in 1835, was the first to make its existence known publicly. Coal was located at Namaimo in 1850 and mining was started in 1852. Until 1861 operations were in the hands of the Hudson's Bay Company and the market was in San Francisco, where coal sold at $28 per ton. Since then mining has been carried on by different companies continuously and the present output from Island mines amounts to 1,700,000 tons per year.

The Geological Survey did some of its first work in British Columbia on the Island. James Richardson began in 1871 an investigation of the coal measures that lasted, with interruptions, for 5 years. He examined the coast line from the head of Comox harbor to Victoria. In this area he found that a series of rocks, 100 miles in length and extending from Brown River to the Saanich peninsula, contained coal seams of various thicknesses at different points. The conclusion was then made that these seams were continuous throughout the greater part of the area and this area was therefore represented on his map as "Productive Coal Measures." Under the circumstances it was easy to believe nearly anything in regard to the unlimited nature of the coal reserves of Vancouver Island. Richardson is praised for the patience and persistency with which he carried on his work. Exception, however, is taken, to his conclusion.

Richardson's area has, for convenience, been subdivided into the Comox, Nanaimo, Gulf Islands and Cowichan areas and his report was followed in 1913 by a detailed and interesting report by Clapp dealing particularly with the Nanaimo area. Clapp also did some work in the Cowichan area. Mr. MacKenzie's report also mentions the Alberni area, but as its possibilities are very slight it will not be further referred to.

Former Tonnage Estimates Excessive

According to Mr. MacKenzie's narrative, "Clapp includes coal seams of the thickness of 1 foot or over to a depth of 4,000 ft., and arrives at a conservative estimate of 1,340,000,000 long tons." This means, according to a popular method of interpreting these figures to the public, roughly 1,000 times the present total annual production. Mr. MacKenzie's comment is that "Clapp's estimate of a very large tonnage for a relatively small part of this area has further strengthened the belief in the enormous coal reserves of the Island."

Both Richardson and Clapp arrived at their conclusions mainly by induction. This is the method employed in Canada by our Men of Vision in arriving at their facts. These are the men who possess that quality known as "Unconquerable Canadian Optimism." Anybody not blindly following this method is branded as a Pessimist, a sort of an Outcast, and is about as welcome in Canadian mining life as was Mr. Blotton in the enlightened circle of the Pickwick Club.

Mr. MacKenzie, unfortunately for his reputation, chose to follow the methods adopted by that "ill-conditioned and presumptuous" Blotton. He was not satisfied with the beautiful sets of figures used by the Orthodox, and, as the different areas have been well opened up for years, he insisted on going below, investigating records of drill holes and interviewing mine officials. In particular he acknowledges the influence of Mr. Thomas Graham, ex-Chief Inspector of Mines for British Columbia and now General Superintendent of the Canadian Collieries (Dunsmuir) Ltd.

Limits of Economical Mining

He found that it is not at present practicable to mine seams of less than 3 feet in thickness. In this connection a recent investigation by the writer may be worth recording. It is to the effect that seams 1 ft. thick do not appear to be mined anywhere. In England seams as thin as about 15 inches have been mined and seams 1 ft. thick might be mined, providing the coal is of first class lump grade, breaks away easily and has a fire-clay floor which can be used as a by-product and in which an undercut can be made cheaply. None of these conditions exist on the Island and, incidentally, they exist in very few other places.

It was also found that 2,000 ft. was about the greatest depth in this area to which mining can now be prosecuted economically. Many other handicaps were also noticed and to quote from the report we find that "the coal in the ground and the coal that a mine may be reasonably expected to produce are not the same. There are always losses, sometimes considerable losses, incidental to mining. A certain amount of coal is left in pillars that are too thin to remove, or that have been crushed by later movements of the strata after the surrounding coal was extracted. Every coal miner on Vancouver Island is only too familiar with the 'rolls' and 'pinches' that make the extraction of coal from certain areas of the mines impracticable, if indeed the movements of the over

* General Manager, Cassidy Colliery, B. C.

lying rocks have left any coal in these thin places. Some areas are so broken by faults that economical extraction is impossible. In one district knobs of the underlying, barren, pre-Cretaceous rocks project through certain parts of the seam. These knobs not only form areas of no value in themselves, but by their effect on the seam as it approaches these old shore-lines interfere with the placing of haulage roads and ventilation. Considerable areas of coal may be lost by mine fires, by excessive gas, water, or by other causes. It is no exaggeration to state that, over considerable areas of some Vancouver island mines, barely 50 per cent. of the coal actually in the ground has been extracted, because of conditions quite beyond the control of the operators."

Mackenzie's Estimates

Further on in the report he also says: "Of the coal mined no insignificant percentage is lost in preparation for the market and in marketing. This extraction factor varies in the different areas, and even between different mines in the same area, so that it cannot be applied readily in a general estimate such as the present one. It is of most vital importance to the coal operator, however, and should be kept in mind by these interested in our future available coal reserves."

We are now in a position to consider what tonnage Mr. MacKenzie found as a result of his investigations. He claims that in the Nanaimo area the amount of "actual" coal, 3 ft. or more thick, and less than 2,000 ft deep, is limited to only 34,070,000 tons. After an extraction factor is applied it will be seen that the assured life to the mines is extremely limited. The corresponding figure for "probable" coal he places at 67,220,000 tons. In order to make a comparison with Clapp's figure he also includes thin and deep coal and every other possibility and yet all this only makes a total of 286,934,000 tons or 21 per cent. of the total given by Clapp.

His findings for the other districts are even more sensational. The big total given in "The Coal Resources of the World" for the Comox district, which is mainly "possible" coal, he finds to be 600 per cent. too large. This district has only 18,900,000 tons of "actual" coal and 39,000,000 tons of "probable" coal. Its "possible" coal above 2,000 ft. depth and over 3 ft. thick amounts to 245,230,000 tons.

The possibilities of coal in the Gulf Islands and Cowichan areas have also been studied in detail. For the former he considers it so improbable that workable coal areas will be found that no estimate for their content is made. For the latter he concludes that it "is not considered a possible source of commercial coal." In regard to the Cowichan area it does not seem clear why it ever was included in the "productive" class. Richardson himself says that "the evidence does not favor the probability of the existence of workable seams of coal in this area." This conclusion was later agreed to by Clapp.

True Estimates of Coal Reserves Required

There has been a great deal of what Mr. Blotton would call "humbug" written in regard to our coal reserves. Not only do our Eminent Authorities add up "actual," "probable" and "possible" estimates as prepared by the Survey and announce to the public that the total represents our coal reserves but, if Mr. MacKenzie's figures are correct, it is evident that some of our own geologists have, at times, announced conclusions that were very wide of the mark. The publication of the MacKenzie report is evidence of a laudable desire to correct errors as soon as they are apparent.

The quotation at the head of this article outlines a new procedure inasmuch as it calls for the recognition of the factors of availability and precision in any coal estimate. What is the object of telling the public that we have certain huge tonnages and suppressing the fact that only a very limited percentage of these tonnages can be recovered? There is also no occasion for haste in regard to the estimation of our ultimate coal reserves. Until we are sure that an area is going to be "productive" it should not be so designated. It is not going to hurt us to leave some resources for coming generations to find. We are leaving them enough debts; let us refrain from including a false statement of our assets.

This heavy reduction in the estimates of our coal reserves at a point where they would be of great advantage, is a big disappointment. The difference between the figures is so great that one naturally asks if it is possible that similar correction will have to be applied to the published reserves of other fields. The advisability of checking up other figures has, however, doubtless occurred to the officials of the Geological Survey.

THE USE OF OXIDISERS IN THE CYANIDE TREATMENT OF CONCENTRATES*

By H. RUSDEN and J. HENDERSON.

Black sand and miscellaneous concentrates (resulting mostly from the clean-up of old reduction works sites) are amongst the by-products received at the Witwatersrand Co-operative Smelting Works. Clean current black sand usually yields a reasonably satisfactory extraction, but frequently fouls the cyanide solutions, charging them heavily with reducing matter. Miscellaneous concentrates are mostly of a much more refractory character, and consignments received from the same source vary considerably from the gold extraction standpoint in the cyanide plant. This irregularity makes it necessary to conduct a preliminary experimental extraction test on all lots of material that may be suitable for cyanide treatment.

The Supervisors of the Smelting Works suggested the use of oxidisers might be beneficial and that a trial be made first on an experimental basis. After making a standard preliminary test with mercury, lime and cyanide, additional experimental trials were made with various oxidisers, which were added after amalgamation and just before the addition of the cyanide.

Permanganate

Permanganate of potash was first tried. A black sand which had shown, experimentally, a very poor yield, giving a residue containing 33.0 dwts. gold and an extraction of 89 per cent. was chosen. Permanganate, nearly equal to the amount required to oxidise the reducing matter (equivalent to 4.4 lbs. per ton of dry material) was added after amalgamation, but before the addition of cyanide. The bottle was well shaken and then the cyanide added. The test was conducted in the usual way and the residue assayed only 3.0 dwts., giving an extraction of 99 per cent. This was quite a startling result, and on being brought to the notice of the supervisors, instructions were given to make further experiments with permanganate of potash, lead peroxide and barium peroxide. The results may be summarised as follows:—

All three gave generally improved extraction; permanganate sometimes slightly increased cyanide consumption, lead peroxide invariably increased cyanide consumption, but barium peroxide usually decreased cyanide consumption. All three at times gave disappointing results. It is to be hoped that discussion may throw some light on the possible reason why the results obtained when using oxi-

* Abstracted from the Journal of the Chemical, Metallurgical and Mining Society of South Africa, June, 1923.

disers at times yield a worse extraction than when no oxidiser is added.

Barium Peroxide

Barium peroxide on the whole gave more consistent results than permanganate or lead peroxide, and instructions were given to make all further experiments using barium peroxide only.

Experiments with varying proportions of barium peroxide were tried, from 1 per cent. of dry weight of concentrate to 0.5 per cent. These experiments showed that, on the whole, 0.75 per cent. gave satisfactory results and was therefore adopted for all further experiments.

The next step was a practical trial. A charge of 10 tons was made up of various lots which had experimentally showed a good extraction with the aid of barium peroxide. This charge was milled and two hundred pounds of barium peroxide were spread over the settled charge in the collector, just before being transferred to the "Brown" tank for agitation. Cyanide was then added and agitation carried on in the usual way. The results showed a recovery of 93.7 to 97.7 per cent. of the gold. Generally speaking, the practical trials agree very closely with the experimental, and must be considered satisfactory when it is noted that in the experimental trials a clean cyanide solution is used, but in the practical, a Works solution that contains a considerable quantity of reducing matter. We cannot say that barium peroxide can be used always with success with any concentrate. From November, 1922, to April, 1923, we have tried experimentally 68 consignments of concentrates with barium peroxide, with the following results:—

Samples giving a satisfactorily increased extraction, 33, or 48.5 per cent.

Samples giving increased extraction, but not sufficient to warrant practical trial, 20, or 29.4 per cent.

Samples giving a worse result than without the oxidiser 15 or 22.1 per cent.

Those giving satisfactorily increased extraction were made up into charges and treated in the cyanide plant with barium peroxide, with good results. The others were treated by furnace methods (pan furnace or sinter pots, with subsequent treating in the blast furnace).

Method of Treatment with Barium Peroxide

We have adopted the following method of procedure in dealing with material that may be treated in the cyanide plant: Any sample, which on the experimental test gives a poor extraction without barium peroxide, and which in other respects is a desirable material for the cyanide plant, is put through a second experimental trial using 0.75 per cent. barium peroxide. If the result is satisfactory that particular consignment is reserved until sufficient material which has been proved to be satisfactory with the oxidiser has accumulated to make up a full charge of 10 tons.

Formerly, roasting concentrates was resorted to when experiment showed that improved extraction was obtained thereby; but it is much easier and less expensive here to use barium peroxide; in fact, our roasting furnace has been dismantled. One undoubted advantage of barium peroxide is that any which enters the solution, precipitates soluble sulphates without adding to the solution any further soluble salt.

The Use of Permanganate

With regard to the permanganate test for reducing matter; we find it a useful guide in the cyanide works as to the degree of "fouling" of the solutions which we may expect, and bleaching powder is added accordingly except when barium peroxide is used. Another interesting point is that the addition up to as much as 1 per cent. oxidiser to most of the samples experimented on did not affect materially the reducing matter present as determined by the permanganate test.

One particular black sand always gives us in the experimental extraction tests a reducing matter figure three times the average of the other black sands. It also consumes more cyanide and lime than the average. But the extraction is generally satisfactory. A charge of this material in the cyanide plant gave the following results in oxygen present in the solution after agitation (we sample our "Brown" tanks just at the end of agitation):—

After first 12 hours' agitation, dissolved oxygen ½ milligram per litre.

After second 12 hours' agitation, dissolved oxygen 1 milligram per litre.

After third 12 hours' agitation, dissolved oxygen ¾ milligram per litre.

Our solutions were at this time very foul. The figure given by the pemanganate test for reducing matter was equal to a consumption of 912 (nine hundred and twelve) milligrams per litre. Yet the extraction was good. The original assay was 12.7 ozs. No barium peroxide was used. The final residue was 8.0 dwts = 96.8 per cent. extraction. The above is typical of our experience with this particular black sand.

In view of Elsner's equation, which includes oxygen as an essential for the solution of gold in cyanide solutions, the above figures are interesting.

These experiments were made under the direction of Dr. Caldecott and Messrs. Maxwell and Pearce.

THE RAND GOLD INDUSTRY

The dimensions of the Rand gold mining industry are not easy to grasp, but their magnitude can be gauged by some recent figures. In June the production of gold was approximately $16,000,000. Native employees numbered 170,000, and there was a marked shortage. The New States mill commenced operation, its capacity being 50,000 tons of ore a month, with provisions for increased capacity. Changes now being made at the Durban Deep mine will give it a milling capacity of 35,000 tons a month. Chief of the mines in point of size are, however, the Crown mines, with a monthly capacity of 216,000 tons, and Randfontein Central with 200,000 tons.

RUBIES AND SAPPHIRES

Rubies and sapphires are corundum crystals of red and blue color respectively. Corundum is a fairly common mineral found in such basic rocks as syenite and serpentine. It is found in large quantities in Eastern Ontario in nepheline-syenite, and in some places blue crystals have been taken out, but none clear enough to be of value as gems. In New York state and New Jersey, rubies have been found in crystalline limestone that is banded with gneiss. In North Carolina, these gems have been found in chlorite, mica, and talc, in a dike of olivine and serpentine. In Burmah, long the producer of the finest rubies, they are found in crystalline limestone and gneiss, but are mostly obtained from placers formed by the weathering of these rocks. Sapphires have been found in a peculiar lamprophyre in Montana, and also in andesite in the same state.

Gem corundum crystals, on account of their great hardness and freedom from weathering, have survived the wear and tear of the years; they should be watched for in panning for gold. They can be recognized by their hexagonal form and hardness; they scratch quartz easily.

Humidification of Mine Air

By THOMAS CHESTER

In the *Canadian Mining Journal* for December 29, 1922, an article appeared by John Moffatt entitled "Coal Dust in Winter," pointing out that during cold weather incoming air currents must be humidified to avoid disaster. The 1922-1923 winter was like other cold seasons in that a number of explosions, unmistakably due to coal dust, occurred in the coal mines of North America. Mr Moffatt pointed out how dry coal dust accumulates in a mine in cold weather and that it collects on the floor, the walls and the roof, on the tops and hidden parts of timber and on everything stationary, thereby becoming a standing menace to the safety of the mine.

Causes of Explosions

Dust explosions occur in factories as well as in coal mines and many buildings have been wrecked in this way. Some examples are flour mills, starch factories, chocolate plants, sugar refineries, aluminum factories, etc. Any dried combustible material can be exploded if suitably pulverized and suitably distributed in air. The more finely divided any combustible substance is, the more rapidly it will burn, whether placed in a pile or distributed in a suitable manner in a current of air. Reducing the substance to a powder results in greatly increasing the ratio of the surface of each particle in relation to its weight or mass. Coal in block or lump form will not burn until the surface is raised to the ignition temperature, and the mass has a retarding effect in absorbing heat from the surface. If a combustible substance is powdered finely enough it will burn almost in the same manner as a gas, and powdered coal is now used as fuel in furnaces on this basis.

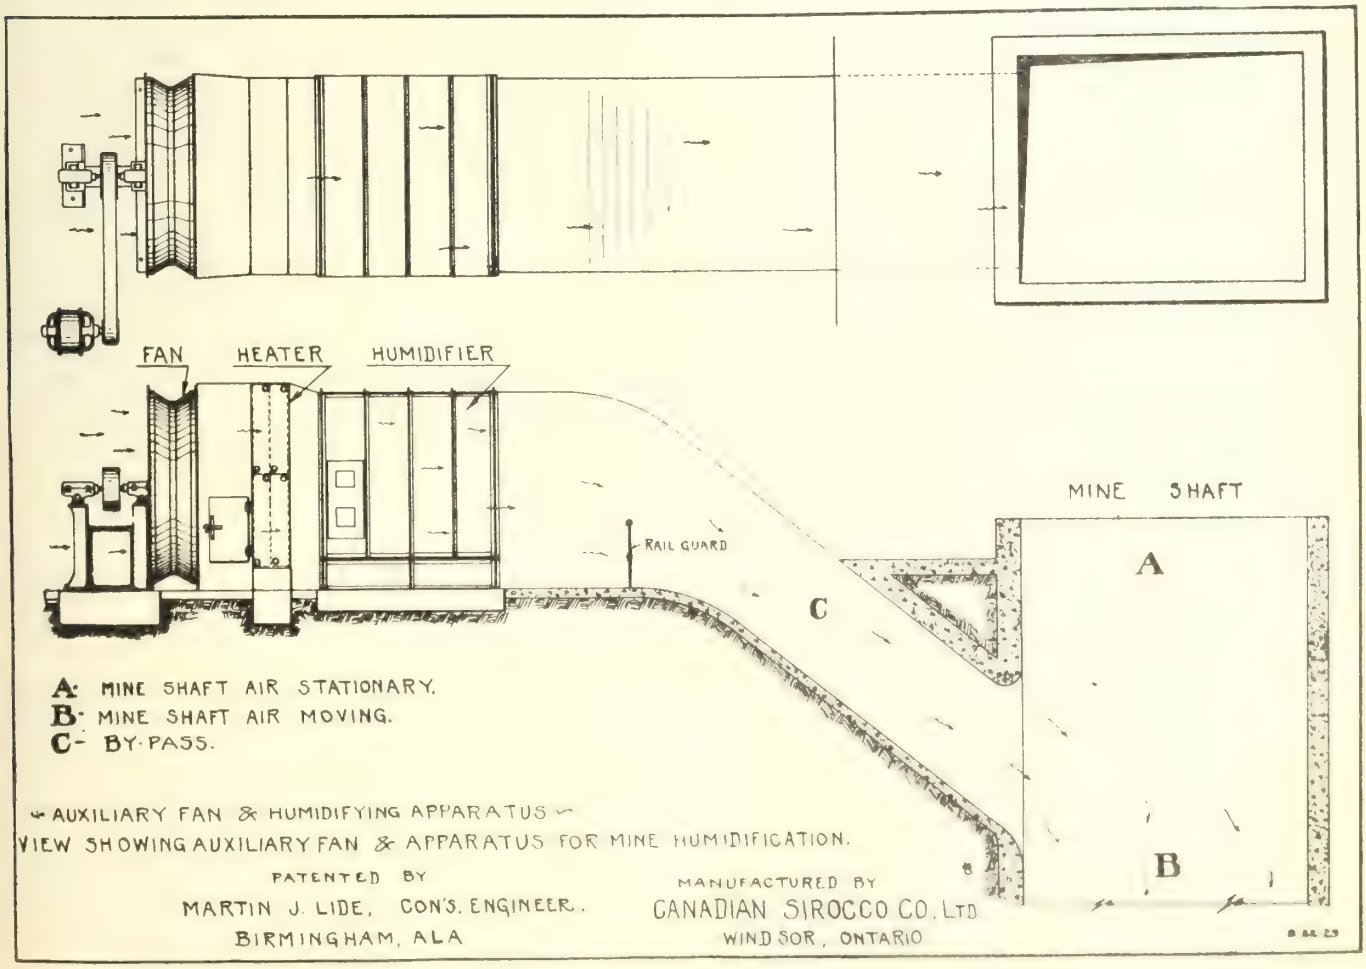
Local explosions occur in coal mines, but these are of very limited extent if gas is not present in great volume or if there is not much dry coal dust distributed along the passages.

Explosions can be produced by the friction of falling rocks on each other or on the rails or other metal, when gas is present, or can be caused by collisions, runaway cars, local gas explosions and blown-out shots. Any one of these can throw enough dust into the atmosphere to start a general explosion, which is intensified as it passes through the mine. After a dust explosion is well under way, the velocity of the detonating wave reaches about 2,000 feet per second with a great development of heat and pressure.

Importance of Vapor in Mine Air

According to a paper read recently to the employees of the Colorado Fuel & Iron Company by Mr. James Dalrymple, Chief Inspector of Coal Mines for Colorado, it appears that in that State during the month of March there is an evaporation of 12,991 gallons, or approximately 54 tons, of water, per 24 hours for each 100,000 cubic feet of air circulated per minute. In January and February the evaporation is even greater but no figures have been published for these months.

This drying out is caused by the air entering a mine in a cold condition and being raised in temperature as it passes along the airways. The effect of this warming is



Lide Humidification Plant

to reduce greatly the relative humidity of the air, which results in water being evaporated from any material containing it with which the air comes in contact. Sprinkling is not always done thoroughly and investigations carried out by the U. S. Bureau of Mines indicate that once particles of coal dust have been thoroughly dried out, it is a difficult matter to get them to re-absorb moisture. In some mines sprays are placed at suitable intervals for delivering finely atomized water to the ventilating currents as the air becomes warmed in its passage through a mine.

Disastrous mine explosions seldom occur in summer because there is a comparatively large amount of water vapor present in the atmosphere in warm weather, as in July and August the outside air contains about 8 grains of moisture per cubic foot. With such a moisture content, if the dry bulb temperature is 90 degrees, the wet bulb temperature will be a little under 76 degrees and the relactive humidity will be about 55 per cent. If this air is cooled to 70 degrees F. it will then be in a saturated condition, that is to say, its wet bulb temperature will also be at 70 degress F., and it will still carry about 8 grains of moisture per cubic foot. If this air is cooled down to 56 degrees it will still be saturated but will then carry about five grains of moisture per cubic foot and the amount of water condensed out of the air will be about three grains per cubic foot, and it is the deposition of this moisture that causes a mine to become wet in summer.

Pre-Heating and Humidifying

The same result can be produced in winter by heating the air to the required temperature and adding moisture before it goes into a mine. If the moisture content of the air is kept sufficiently high, there will be practically no evaporation and very little drying out of coal dust. It is not, however, necessary to pre-heat and humidify the intake air to a summer condition, as all that is needed is to prevent the evaporation of water within the mine, and this can be done if there is no subsequent warming after the almost saturated air enters a mine.

The apparatus used for conditioning the air entering a mine can be employed also to super-saturate the mine air whenever required, that is to say, during holidays or whenever the mine is shut down. This is done by raising the air temperature to permit of picking up enough water to raise the dewpoint temperature above the mean temperature of the mine. When this is done, water will be deposited in the form of dew exactly as occurs in mines during the hot, humid weather of summer.

As previously stated, moisture can be added to mine air by water sprays at suitable intervals; but the common sense thing is to concentrate the air-moistening equipment above-ground, where it can be given adequate attention. In this way it can be controlled easily and any suitable variations in temperature and relative humidity can be produced at will.

When a mine is ventilated by a fan operating as a blower, the air conditioning apparatus can be placed between the fan and the downcast shaft or intake drift. When a mine is ventilated on the exhaust principle the application of the humidifying device is not quite so simple, as it is not desirable to use double doors or ar locks for the purpose of regulating the air flowing into the mine after being suitably conditioned, because this would interfere with the progress of taking out coal.

The Lide System

Mr. Martin J. Lide, Consulting Engineer of Birmingham, Alabama, has developed and patented a system whereby this difficulty can be overcome very satisfactorily. The diagram herewith shows a Lide humidifying system applied to a shaft mine ventilated by a main exhaust fan in the regular way. It will be noted that a Ventura Disc Fan blows air through a heater and then through a humidifier and thence down a sloping by-pass, which connects with the mine shaft some distance below the collar. In this way suitably conditioned air can be blown into the downcast shaft and will then travel through the mine in the regular way under the influence of the depression in pressure caused by the main fan.

By reference to the diagram it will be noted that there is a neutral zone between the bypass outlet and the collar of the mine shaft. No particularly bad effect would be caused by a little cold, dry air being drawn down the mine shaft direct from the outside atmosphere; but, if necessary, this could be avoided by speeding up the Ventura Disc Fan to produce a surplus above the amount of air handled by the main exhaust fan and this surplus would be vented from the bypass outlet through the collar of the main shaft to the atmosphere.

It is not sufficient to blow exhaust steam into the air entering a mine, as this produces a very wet condition and causes falls of the roof from the combined effect of water and heat. With the Lide system, however, the air is merely tempered or warmed to a little above the mean temperature of the mine and is cooled somewhat during the subsequent evaporation of water from sprays in the humidifier. If necessary, exhaust steam can be added to the tempered air instead of using atomized water, and in either case this can be done under the control of sensitive instruments so that both the temperature and relative humidity can be maintained constantly as required. This is a somewhat unneccessary refinement, and the main purpose of the Lide system is to make it possible to raise the intake air temperature and relative humidity sufficiently to reduce the tremendous drying out that occurs normally in mines during winter.

It is necessary to have a considerable amount of exhaust steam available for this purpose and therefore mines equipped with power plants can readily instal Lide humidifying systems. However, mines that use purchased power can instal second-hand boilers for making low-pressure steam and low-grade and waste coal can be burned by installing forced draft fans, which makes it possible to operate such boilers at a low cost.

A considerable amount of research work has been done to ascertain the most suitable atmospheric conditions and it has been determined that comfort is dependent upon the wet bulb temperature and air motion. The wet bulb temperature is the real index of the amount of heat in air, and the relative humidity is secondary in importance. The cool air within a mine is more comfortable if it has a high relative humidity than if it is very dry, because the wet bulb temperature is higher in the case of air that is nearly saturated.

If the dust given off by the coal cutting machines it wetted down as soon as produced and if drying out of the mine generally is prevented in cold weather, it will be found that serious explosions can be almost entirely eliminated.

GRAPHITE

Of the hundreds of graphite deposits known in Canada, very few have proved to be of economic value. The difficulty lies in separating the graphite from the other minerals, such as quartz and mica. For the finer grades, for use as lubricant, in lead pencils, and for crucibles and electrotype making, everything of a gritty nature must be removed, and also all minerals that would tend to lower the fusion temperature of crucibles. This concentration is easy with some deposits, particularly with "flake" graphite disseminated in crystalline limestone. Fine grained or "amorphous" graphite is not so easily purified.

The A. I. M. M. E. Excursion

Report of the Trip to Sudbury, Cobalt, Kirkland, Porcupine and Thetford Mines

The twelve days' excursion of the American Institute of Mining and Metallurgical Engineers through Ontario and Quebec, concluded in Montreal last Friday, was, by consensus of opinion, both Canadian and American, a most successful tour. From the time the forces from the South, over a hundred strong under the leadership of Dr. E. P. Mathewson, were joined in Toronto by the cohorts of Canada under Mr. Dresser, until the visitors forsook the stronghold of liberty on Friday, their time and attention were occupied just as fully as they chose with visits to mines,

DR. E. P. MATHEWSON
President, A.I.M.M.E.

mills and smelters, technical discussions and sightseeing tours. They have seen a corner of our Dominion, and have departed with the salutation, "au revoir."

On arrival in Toronto on August 20th, the excursionists were joined by an equal number of Canadians, and all were entertained by the City of Toronto at luncheon. Mayor Maguire welcomed the guests, and Hon. W. F. Nickle, Attorney-General for Ontario spoke of the mutual good-will and understanding of our two national communities. Hon. Charles McCrea, Minister of Mines for Ontario, extended greetings on behalf of the mining fraternity, and announced that he and members of his Department's staff would accompany the excursion throughout the province.

The evening was occupied by a reception in the Parliament Buildings at which Mr. McCrea presided, with the assistance of Mr. Nickle, who outlined in a comprehensive address the possibilities of the north country, indicating the influence our cordial relations with our American neighbors would have on its development. Dr. Mathewson and Dr. A. S. Dwight gave the American view of these same happy international relations.

Special Bulletins of Department of Mines

One feature of the facilities provided for the visitors by the Ontario Department of Mines deserves special mntion. Two bulletins were printed for the occasion, both being parts of the compendious report on the Cobalt area prepared by Mr. C. W. Knight and associates. Bulletin No. 47, "Milling and Metallurgical Practice in Treatment of Silver Ores at Cobalt," by Fraser D. Reid, J. J. Denny and R. H. Hutchison, describes the milling problem, recounts the story of its solution, and describes fully present practice by both the gravity and flotation method, as exemplified in the Coniagas mill, and cyanidation, as at the Nipissing. This report will form a permanent and very valuable record of one of the outstanding accomplishments of Canadian metallurgists.

Bulletin No. 48, "The South Lorrain Silver Area," by Cyril W. Knight, is a 55-page excerpt, complete with illustrations and maps, from Mr. Knight's report. The information and ideas made public in its pages will aid materially in the rational development of this important silver camp. Dr. Miller worked nights and Sundays to get these two bulletins through the press in time for the excursion.

The Sudbury District

Tuesday morning found the excursion's special train at Coniston in the Sudbury district. In spite of a downpour of rain the inspection of the nickel mines and smelters proceeded according to plan. Dr. Corless and his staff showed the visitors over the Mond Nickel Company's model plant and town, where twelve years ago there was merely a favourable railway intersection in the midst of the forest. The British America Nickel Corporation's smelter at Nickelton and the adjoining Murray Mine, where the nickel ore was first disclosed in a railway cutting forty years ago, were inspected next, under the guidance of Mr. Hibbert and his aides. The blast-furnaces here reduce the 3 per cent. ore to a 12 per cent. matte, which is raised to 80 per cent. nickel and copper in basic converters for shipment to the refinery at Deschenes.

The terminus for the day was Copper Cliff, the centre of the International Nickel Company's operations. The famous Creighton Mine hard by has yielded already ten million tons of ore containing 4 per cent. nickel and 1½ per cent. copper, and its reserves are much in excess of this vast amount. This illustrates the magnitude of the district's known resources. The problem confronting our nickel industry is to find adequate uses for its products. Before the war 85 per cent. of the world's nickel was used for war purposes and 15 per cent. in industry. Today these figures are reversed. The present activity round about Sudbury can indicate only that nickel is a vastly more impor-

tant industrial metal than we formerly considered it to be.

Hon. Charles McCrea Outlines Policy

During the course of a smoker in the evening, presided over by Mr. John L. Agnew, Mr. McCrea made an important pronouncement on behalf of the Ontario government. In outlining the policy of the Department of Mines he stressed the need for stable, just and discriminating administration. Only thus can we attract and retain the interest of the investors whose aid we require to find and develop our mineral resources.

"Mining taxation," said Mr. McCrea, "bears definitely upon the welfare of the mining industry. Every government must have a revenue but that revenue should be raised in such a way as to hamper as little as possible legitimitate enterprise or industry. A mining tax should be fair and one which appeals to the natural sense of justice. Our present system is a tax on net profits, after all expenses are met. It is difficut to imagine a fairer or less onerous method of taxation or one better adapted to meet fluctuating conditions from year to year as profits rise or fall.

"A mining tax should not discourage development. The present tax meets this requirement. In the early years of a mine, when it is all outgo and no income, the mine pays no tax. Not until it reaches a productive and profitable stage does the tax take effect, and then the mine can afford to pay it. Further, a tax on profits does not operate against the opening up of low-grade deposits, or those in which the chance of success is, to a certain extent, speculative.

"A mining tax should be stable. The amount of taxation must have relation to the amount of revenue the government requires but frequent or violent changes in the rate are to be avoided. Better have fifty mines at work yielding a moderate profit and paying a moderate tax than five mines operating bonanzas with lower grade ore bodies lying unworked."

Mr. McCrea mentioned also his intention of extending the scope and the extent of his Department's geological work, and referred briefly to the fact that upon the provincial authorities rests the responsibility for suppressing fraudulent enterprises without impeding honest business. Mr. Thos. W. Gibson followed with a clear and concise survey of the progress of the mining industry in Northern Ontario, and Mr. T. E. Godson enlivened the proceedings in a characteristically humorous explanation of his duties as Mining Commissioner.

Cobalt and South Lorrain

During Wednesday and Thursday the excursionists found how thorough had been the arrangements made for their entertainment and instruction at Cobalt and South Lorrain. The mills and mines of the camp were thrown open for inspection. Of particular interest was the unique display of ore specimens gathered at the Nipissing mill from the whole camp. All the silver has not gone out of Cobalt yet — not by a long shot! In South Lorrain similarly spectacular ore was inspected in place in the Woods vein.

During a technical session on Wednesday evening, Dr. Miller recounted incidents from the history of Cobalt, with which he has been associated so intimately from the beginning. He stressed particularly the fact that the study of the geology of the Cobalt region has provided the key to the rocks of a large part of Northern Ontario. Dr. J. Mackintosh Bell, to whom is due in large measure the renewed development in South Lorrain, pointed to the concomitant result in the economic sphere; Cobalt's development has hastened and facilitated the whole of Northern Ontario's subsequent mining activities. The mining men of Cobalt earned the thanks of the visitors, both Americans and Canadians, for the pains they took to prepare and carry through an unusually fine programme.

The Gold Camps

The inspection of the Kirkland mines and mills on Friday was preceded by talks by Mr. P. E. Hopkins on the geology of the camp and by Mr. Jas. G. McMillan on the mining methods. The model mills placed at intervals along the three-mile ore-zone were the feature that attracted most attention. The camp's metallurgy is an exact science, and its mills are practical perfection.

Next morning, Saturday, was occupied in examining the Abitibi pulp and paper mill at Iroquois Falls, which, with an output of 25 cars of newsprint a day, is the largest mill of its kind in the world. During the afternoon a first view of the "big three" mines of Porcupine was afforded, and a study of these and some of the lesser properties occupied the next day. Here, as in the other camps, the resident committee had provided every possible facility to entertain and instruct the guests during their thirty hours in this, the most important gold mining district on the continent. The expressed opinions of some of the visitors with world-wide experience indicate the world-wide attention this camp has drawn. Mr. R. W. Bissell says it shows clear evidence of long life and of mining at great depth. Messrs. J. W. Mercer and J. V. N. Dorr admire its metallurgical practice and point out that already McIntyre practice has been copied in Ecuador.

Thetford Mines

After a day's travel through northern Quebec on the Transcontinental the excursion reached Quebec, where sight-seeing was the order of the day, a much needed relaxation after the strenuous week just passed. Hon. Frank Carrel and Mr. T. C. Denis received the guests on behalf of the Quebec Department of Mines. Thetford was the next stop, on Wednesday, where a committee under the guidance of Mr. Norman R. Fisher had prepared tours of inspection through mines and mills. The next day was occupied with technical sessions in Montreal, and Friday August 30th, the last day of the trip, was spent appropriately in trips by car or by boat in the environs of Canada's metropolis.

Hon. Charles Stewart's Profession of Faith

"I believe that the future welfare and prosperity of this country depend fully as much on mining as on agriculture, — and that is saying a good deal," declared Hon. Charles Stewart, Federal Minister of Mines, at the banquet that concluded the excursion. Mr. Stewart has learned well this fundamental lesson since taking over the Department of Mines in Ottawa. Both he and the subsequent speakers, Hon. Charles McCrea and Mr. T. C. Denis, wished the visitors godspeed on their return and invited them to come again.

The sentiment of the Canadians who accompanied the excursion was well expressed at this banquet by Mr. John A. Dresser, who, after pointing out that among the guests he recognized as former fellow Canadians

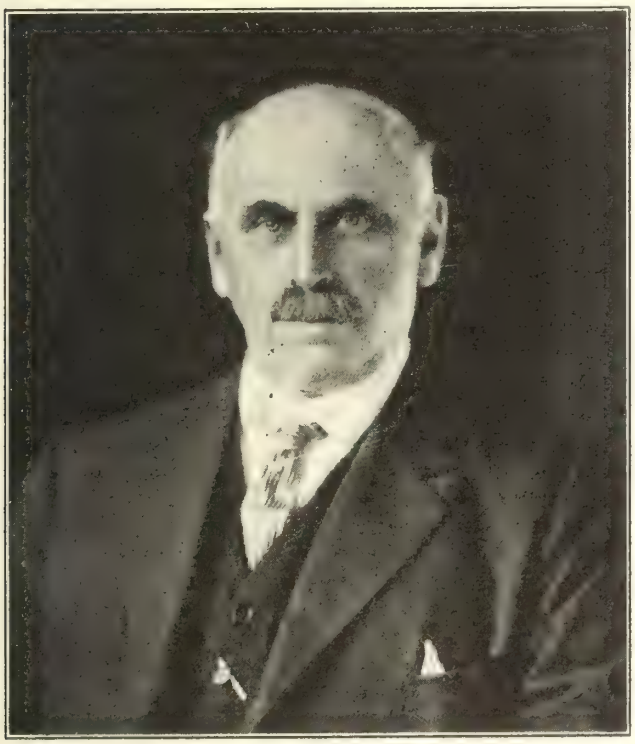
the four eminent metallurgists E. P. Mathewson, E. H. Hamilton, W. J. Hamilton and Forrest Rutherford, went on to say:

"In reviewing the events of your successful excursion, words of congratulation are in order. The design of your tour was well chosen. It has been limited to a radius of, say, 48 hours travel from New York or Chicago and yet the variety has been, I trust, sufficient for the purpose of so short a visit.

"For the pleasure of the trip, which depends so much on a arrangement of details, a huge debt is owing to the indefatigable care of your Secretary. With characteristic kindliness he was unfailing in provision for every step. I wonder if he realizes to the full his success in bringing this large party of adventurers through this long and hazardous tour in the wilds of Canada without mishap, if not disaster.

Mr. Dresser Outlines Opportunities in Canada

"But seriously and sincerely, let me in few words convey the hope of our Institute that your visit may have given pleasure to you, as it has to us, and that



MR. JOHN A. DRESSER
President, C.I.M.M.

you may carry to your homes only pleasant recollections of this little 'peep' into two small corners of two of our Provinces. I will not repeat what you have seen —if it interested you, may you soon come again and see more. We have several Provinces and they have many corners of interest.

"Some wag has said that Canada is alright only that it is too big for its population. Others compare us to a frontier farmer who has more land than he can fence or till. Thanks to you, our good and only neighbor, we do not need fences. But when it comes to utilizing our vast heritage, which the cost of four long years of destructive warfare compels us to hasten, serious difficulties over-hang our Committee of Ways and Means. We seem to have more Ways than Means. For instance we have railways and waterways, and highways, but we lack means to use them. That is to say, we have expended largely on transportation facilities and water power developments, and now in the shadow of the Great War we lack capital to take advantage of the opportunities these works have created for us. Our farm and forest production is steadily advancing; but to make our mineral resources earn more for the benefit of our country and our people is one of the great tasks now before us.

"This is, of course, an inevitable stage in all pioneer life, — a life which, by the way, it is frequently said, does not pay. The truth of this statement, however, depends on the ideal. All people worth while have always struggled to leave their country and the means of life in it better than when they entered it, and we propose to do the same. Your thoughtful humorist, Artemus Ward once described the attitude of the man without ideals as saying of Christopher Columbus. 'Chris. meant well enough, but he was an awful fool to spend all that money just to discover America. What was he going to do with America when he had it all discovered? If he had put the money into Bay State Gas or Manhattan Traction Stocks he would have been able to live on Fifth Avenue long ago.'

Common Interests of Americans and Canadians

"However, we expect to grow and to become a nation of importance in the world. We do not intend to sell our country, but we are glad to have our neighbors come and help develop it and to share in the profits of its development. In every Province of Canada we want capable people, people who know an opportunity when they see it, and seeing it, have the courage and efficiency to make use of it, to our mutual benefit. We offer to you the rights and privileges that we ourselves enjoy. We have a surplus of unused resources, you, a surplus of capital. Neither is useful until it is employed. Employ your capital in utilizing our resources and the reserve side of the bargain will afford a profitable opportunity to each of us. It is the familiar mining contract of putting the property against the money to work it, which is always based on mutual confidence.

"Descended from a common ancestry, a race of pioneers and traders, we are closest neighbors in place and kin and creed. The common ideals and warm sentiments that bind your great country with the great Empire of which we are a part is the strongest safeguard of civilization in the world today. Let it be strengthened by our best efforts in sympathetic understanding and neighborly co-operation. In a word, let us live the course forecast for us in the last public words of your late President Harding. To this end, no more practical and effective step could be taken than the visit with which you now honor us. We thank you for it. We wish you God-speed and an early return."

In thanking all those in Canada who had contributed to the success of the excursion, Dr. Mathewson made special mention of the help, both personal and by means of printed reports and maps, afforded by the three Departments of Mines at Toronto, Ottawa and Quebec. This official aid was, he said, a new experience to the touring members of his Institute, and had done much towards making the Canadian excursion a landmark in the memories of himself and his confrères.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

QUEBEC

Despite the handicaps of a late season, transportation difficulties beyond the ordinary, and the prevalence of heavy overburden, the prospecting season in northwestern Quebec has been successful already. The bush fires have cleared the surface in places and a more comprehensive view of outcrops was thus obtained. If there have been the inevitable disappointments, there have been also enough "finds" of importance to justify the confidence that this section of Quebec will have important gold mines.

Lake Fortune has the elements essential to mining and milling operations. The ultimate extent of the ore-bodies cannot be foretold. Elsewhere in the vicinity it has been ascertained gold occurs over extensive areas.

One block of ground on which high hopes were based has been abandoned by those who held the options, who did not see their way clear to meet the second payment. Offsetting this is the knowledge that a large, new showing on the Chadbourne claim of the Noranda Mining Co. in Rouyn township promises well.

In addition there is the fact that diamond-drilling on the Stabell property on the Harricanaw has disclosed a shear zone in which the values indicated have prompted new owners to sink a shaft to a depth of 500 feet. According to report, the sixteen short boreholes put down have made the Stabell more than a prospect. The results from twelve of these, 100 feet apart, and the remaining four, spaced at 200-foot intervals, have sustained the favorable opinion of those who had examined the outcrop and considered it of great promise. The twelve holes were stopped at 150 feet, and the four went to 300 feet. Eight of them were under the section sampled repeatedly during recent years and its extension under a swamp. The shear zone where penetrated is said to be about 60 feet wide. One section at 300 feet depth gave $26.00 over 19 feet. In another place ten feet ran $7.50.

More recently a discovery has been made between Rouyn township and the Transcontinental Railway. Should this prove to be a valuable "find," it will have a decided influence in extending the width of the east-and-west strip of good prospecting ground.

The Lake Fortune discovery has stimulated activities in the vicinity. An Ottawa syndicate composed of Redmond Quain, Frank Ahearn, Mrs. Ahearn and R. C. Gamble, who hold an area of 1,100 acres between Olier and Renaud Lakes, adjoining the Lake Fortune property on the south and east, have sent in a gang of men to do development work. This property covers a large intrusion of porphyry, but, unfortunately, the surrounding rocks of the Temiskaming series are covered with rocks of the newer Cobalt series.

The Irma Oil Development Co. is building a rig near Irma in Sec. 28, Tp. 45, R. 9 W of 4th meridian, in east central Alberta, and will put down a well with a rotary drill.

NORTHERN ONTARIO

The A. I. M. M. E. Excursion at Cobalt. — The visiting party from the American Institute of Mining and Metallurgical Engineers has completed its tour of the Northern Ontario mining camps. It was unfortunate that the weather was not better; it was cold and rainy most of the time. However, there was one good day in Cobalt, at least, which was fortunate as it was the day on which it had been arranged to take the party to south Lorrain and for a boat trip on Lake Temiskaming. One of the most interesting features of the Cobalt trip was the display of silver ores on view in the Nipissing refinery. The specimens were contributed by all the different mines, and embraced nearly all the minerals found in the district. It is probable that nowhere else in the world could such a display of silver ores be got together. The Hon. Chas. McCrea, Minister of Mines, spoke in both Sudbury and Cobalt, outlining the work of the Department. He laid stress upon the fact that it was the desire of the Government to create a feeling of confidence in the mining industry and of stability with regard to titles and taxes. The Government does not propose to change the mining taxation, so that there will be no uncertainty in the minds of foreign investors regarding this important item. Mr. McCrea also stated that it would be the policy of the Government to build roads to promising mining districts and to construct railways where the developments warranted. The work of the Province's geological staff will also be extended, and an effort will be made to have geological surveys made of promising districts that justify work by the prospector.

Porcupine — Several Porcupine companies have extensive shaft sinking programs underway at present. Work has been started on the 1000-foot, three-compartment incline shaft of the Davidson. Electric energy for this work is being obtained from the Great Northern Power Company. The Goldale shaft has reached 900 feet, and will shortly be at the 1000-foot level where development work will be undertaken to explore the ground under the discovery on the 500-foot level. On the Newray, adjoining the Goldale, preparations are practically completed to carry the shaft to a considerable depth, and it is expected that it will also reach 1000 feet. The shaft on the Rochester property is down 550 feet, with a level at 500 feet, but no extensive development work will be undertaken until the shaft has reached 1000 feet. The McIntyre is considering the sinking of a new shaft, which eventually will reach a depth of 5000 feet, but so far nothing definite has been done regarding this work.

The split up of of the Dome shares has been delayed for several weeks, due, it is said, to the failure of the engraving company to deliver the new certificates. When these are ready two shares of the new stock will be issued for each share of the old, and it is expected that about that time the company will list its shares on the London market.

The Hollinger has declared the regular four-weekly dividend of 1 per cent, payable September 10th to shareholders of record on August 23rd. Although additional machinery is being installed in the mill, the management does not propose to increase the output until an ample

supply of electric power is available. The management evidently looks forward to another power shortage next winter, although conditions throughout Northern Ontario are very favourable, as the season has been exceptionally wet and more rain has fallen than for several years. The Northern Canada Power Company has several thousand horsepower available for distribution and has not been forced to draw on its storage basins. The machinery for the Hollinger power development on the Abitibi River has been ordered, but so far there is little activity at the power site.

At the Vipond, No. 10 vein has been cut on the 6th level, where it shows substantial values. This is the vein found a few months ago, which has now been located at several points between the surface and the 1,000-foot level. It is of higher grade than the other veins so far developed on the property, and it was this discovery that led the management to make preparations to resume milling. The entire treasury stock of the company has been taken up under the terms of the option entered into last year, and as a result the company is amply financed and is expected to enter the producing stage with approximately $50,000 cash on hand.

Matachewan — Only a small amount of work is being done in the Matachewan area. The work on the British Matachewan Gold Mines is being confined to diamond-drilling. In view of the statements made by the promoters who were endeavoring to sell the stock of this company, it was to be expected that more active progress would have been made. According to these statements the company has a large amount of ore blocked out, and is, in fact, a second Hollinger, needing only a mill to make good its claims. The company, however, seems satisfied, for the time being at least, to confine its main efforts to selling stock. The Matachewan General Mines Limited is the name of a new company which owns 63 acres between the British Matachewan and the Davidson, and it is proposed to explore this by diamond-drilling. On the American Matachewan claims, only assessment work has been done, but a small gang of men has started work on the Powell Matachewan.

Market Manipulation — The recent fluctuations in the stock of the Hattie and Beatty mines has resulted in legal actions for substantial amounts being taken. Dr. W. P. St Charles entered into an agreement with John K. Papassimakes to buy up all available Hattie and Beatty stock for their joint account. Dr. St. Charles claims he was misled by reports of assays submitted by Papassimakes, which he believes to be fraudulent, and was further misled by representations that English capital had become interested. Relying on this, he entered into an agreement with Papassimakes and now claims that Papassimakes unloaded his personal holdings on the market and refused to carry out his obligations as to a joint purchase. Hattie stock recently dropped from 45 cents to 8 cents a share.

NOVA SCOTIA

Coal Output Climbing The output per man at the mines is much higher than it was before the strike, and efforts are being made to help it to climb still further. Workmen are making satisfactory wages, which brings contentment, and most of them are fast forgetting the struggle through which they have just passed. It is evident that, barring trade depression, industrial conditions will be much better in this district than for many years. There is, however, a slight reaction towards the malcontents, due to several causes. One of these is the refusal of the legal authorities to continue the injunction against the district officers ousted from position by John L. Lewis. Another is that the time is drawing near when the new wage agreement will be made, and there are those who believe that strong agitation for the 1921 wages will be successful in splitting the men into two separate bodies. The irreconcilables who believe this are most active among the workmen, and their activities are not to be held lightly, for they will push to the utmost their efforts to form a new labor organization when conditions are ripe. That such a union will have for its purpose industrial and political control and will use such destructive weapons as strike and sabotage, there can be little doubt. However, pitted against them are able and experienced leaders from the United States, who know the game and how to play it, and chances for the success of the "Red" campaign will be slim indeed.

Mainland Locals Want Election — There are rumors that the mainland Locals are anxious for an election, and the extreme element are using this to force the hand of John L. Lewis to bring on an election at an early date. This will not be done, and it may lead to Cumberland and Pictou county locals separating from the main body in Cape Breton. This might be a blessing in disguise to the miners of both counties, who for upwards of two years have been very much dissatisfied with the actions of their brother workmen in Cape Breton.

General Works Committee Elected — The steel industry had also settled down to normal conditions, and both the employer and employees are beginning to find that it is good for all to dwell together in unity. The workmen of Sydney steel plant have now elected their representatives on the General Works Committee, and these are getting down to business in earnest. The fine spirit shown by all is notable, and however imperfect the machinery for handling labor disputes may be at the beginning, the "get together" feeling will weld and hold both parties in one body until there is perfect union. Even if some component parts of the machine may not fit well and may cause some little friction, yet constant lubrication will tend towards smoothness and harmonious operation. The new co-operative step has enlivened the hope of the whole community, and all are working together with a will to better the conditions existing on the steel plant, and to make good-will the paramount feeling among all the workmen.

BRITISH COLUMBIA

Stewart — Work on the Dunwell Group of mineral claims, near Stewart, Portland Canal District, following the recent uncovering of a promising body of ore, is being carried forward with all possible dispatch. Drifting on the two veins in No. 2 tunnel goes on unceasingly and a considerable quantity of ore showing argentite and native silver is being put aside for shipment. At the portal of No. 3 tunnel a site is being cleared for the erection of mine plant, buildings, etc. and simultaneously a good trail is being constructed to the property. A compressed air pipe line, 7,500 feet long, is being laid from the old Portland Canal Mine compressor plant up the hill to the Dunwell. It is expected that all preliminaries necessary to permit development throughout the winter will have been completed in the course of a few weeks.

The operators of the L. & L. Group have been encouraged by breaking into high-grade ore when driving

a short cross-cut a few feet from the face of their tunnel.

Some first-class specimens of fine-grained galena, the quartz gangue of which is stained with silver chlorides, are reported to have reached Stewart from an outcropping on the north fork of the Marmot River. P. E. Reese is the discoverer, and old time prospectors state that the samples recall the rich silver ores of Colorado and Montana.

The Granby Consolidated Mining & Smelting Co. is reported to have abandoned its options on the George and the Sunshine Groups, copper properties situated respectively on Bear River and Glacier Creek, Portland Canal District. The Company continues to explore and develop the Outsider Group, Maple Bay, which shipped regularly some twenty years ago when controlled by the Brown Alaska Mining & Smelting Co., which operated a copper smelter at Hadley on Princess Royal Island, Alaska. There are two well defined veins, one of which can be traced for half a mile up the mountain. The copper content is said to average 2 per cent. The Company is understood to have planned much diamond-drilling as well as other development.

Smithers — Following the announcement that the Guggenheims have acquired a majority interest in the Henderson Group and other of the Duthie holdings at Hudson Bay Mountain, near Smithers, northern British Columbia, comes the report of the location of a large copper deposit on Copper River in the same district. It is alleged by another prospector that he has found tin-bearing ore on Porphyry Creek, near East Hazelton. If this should be confirmed it will be something new and unique for this part of western Canada. Samples have been submitted to the government mining engineer for test. The provincial government's new road from Smithers to the Duthie mines is expected to be ready for use within a week, which will materially improve mining conditions.

Rossland — The highest grade ore ever shipped from a lode mine in the interior of British Columbia is reported to have been produced by the "Golden Drip", which adjoins the "I.X.L." in the Rossland district. From time to time gold quartz shipments have been made from the "I.X.L.", the returns from which have been astonishingly high. Unfortunately the operators have not been able to find more than stringers and pockets of this highly valuable quartz, but their occasional finds have repaid the work involved and the promise of more ore further on has given an even greater zest than usual to the development work. The adjoining claims, known as the "Golden Drip" Group, are being developed by M. E. Purcell, formerly general manager of the Rossland Mines of the Consolidated Mining & Smelting Co., and the production here of ore similar to that found on the "I.X.L." is considered both significant and encouraging.

Promising Silver-Lead Prospects—George H. Aylard of Victoria ,president of the Standard Silver-Lead Mining Co., has returned to the Coast after visiting the Ivy Fern Mine, Cultus Creek, Kootenay Lake, and the McAllister Mine on the north fork of Carpenter Creek in the Slocan District. Mr. Aylard's company is developing both these properties, having a half interest in the former and a bond and option on the latter. He was accompanied on his inspection by W. H. North, general manager of the company. On the Ivy Fern a strike has been made which is regarded as important. Four or five feet of good milling ore has been uncovered under conditions indicative of substantial reserves. A plant is to be installed on Cultus Creek to supply power, and further development has been ordered to be commenced. Work on the McAllister Mine also is said to be making satisfactory progress. The company of which Mr. Aylard is the head has a good-sized fund for the opening up of just such properties as those instanced and it is confidently predicted that one or the other, or both, of those prospects soon will be put on a shipping basis.

Kimberley Mill Completed — The concentrating mill of the Consolidated Mining & Smelting Co. at Kimberley has been completed and all is reported to be ready for the treatment of the product of the Sullivan Mine close to the mine's portal, a change that will lighten the heavy burden that has been placed upon the Trail plant, as well as effecting a substantial saving in transportation charges. The new mill covers some twelve acres, has a capacity of 2,500 tons of ore a day, and its cost is placed at approximately $1,500,000. Bunkhouses for the accommodation of 150 men also have been constructed. The cooking for the camp is done by electricity.

The new concentrator equipment commences with a coarse crushing plant capable of crushing 7,500 tons of ore every twenty-four hours, with a 1,000-ton receiving bin from the mine and a 2,500 ton railway bin, to receive ore from the crushing plant. The latter bin discharges into standard railway cars and is transferred to the mill three or four miles away. It was necessary to locate the mill some distance from the mine in order to get sufficient impounding gounds for tailing and a suitable mill site.

The ore is weighed over standard railway scales and is discharged into a 1,000-ton receiving bin in connection with the fine crushing plant. This plant reduces the ore to ½ inch and has a capacity of 7,500 tons every twenty-four hours. The product of the fine crushing plant is discharged into the 2,500-ton mill bin from which it is drawn to feed the mill. The mill will have a capacity of from 2,500 to 3,000 tons per day, the process being selective flotation, to remove first the lead content of the ore as a high-grade lead concentrate; second, to remove the zinc with a small part of the lead, as a zinc concentrate.

The mill is equipped to table any of the products when necessary. The process has been tested thoroughly in the Trail concentrator, which has been handling from 1,000 to 1,100 tons of ore per day for over a year, and is the outcome of research work done by the Consolidated Company in their own plant at Trail. A further advance in progress for Trail was attained when, outside of the primary crusher and the motors, practically all the machinery for the "Big Sullivan" mill was made in the Consolidated shops. In order to accomplish this, it was necessary to build a new foundry and to add a considerable amount of machinery to the various shops. All the buildings of the Sullivan mill and the ore bins are composed of steel and concrete. The roofs are made of 2 x 4's on edge covered with Barrett specification roofing, with tar and gravel surface, reducing the danger of fire to a minimum.

Lillooet — It is difficult to obtain authentic information of mining activity in the Whitewater district, which lies north of Lillooet in the Clinton Mining Division, but all reports speak of important results in the development of old prospects and of the location of many new claims. The Whitewater Gold Fields Ltd. have a crew of twelve men at work on the Taylor claims, the promising nature of which first directed attention to the district. A Ross mill has been installed and an assay office built and equipped. General camp accommodation also has been provided. This work appears to have

occupied most of the time of the men up to the present. The intention is to operate throughout the winter and it is assumed that shipments of ore will be made over the snow to the Pacific Great Eastern Railway at Williams Lake.

The Patricia Group in the same district, was bonded by Messrs. Trites, Wood and Wilson, who have had men under competent direction driving a tunnel. They are said to have gone in 200 feet with results that justify expectations.

A. W. Lohmann, of Tacoma, Wn., who spent several weeks in the Whitewater, is quoted as comparing it to Cripple Creek, there being "the same sort of formation in which the gold is free and highly concentrated."

Trail Ore Receipts — Ore receipts at the Trail Smelter of the Consolidated Mining & Smelting Co. for the week Aug. 7 to 14 totalled 6,091 tons, as follows:

Alamo, Alamo	99 tons
Bell, Beaverdell	45 "
Black Rock, Northport	188 "
Company Mines	5,031 "
Cork Province, Zwicky	42 "

Standard, Silverton	36 "
Total	6,091 "

POSITION OPEN FOR GEOLOGIST

The Civil Service Commission, Ottawa, have announced that applications will be received until September 20th for the position of geologist, as follows:

5957.—A Geologist for the Geological Survey, Department of Mines, Ottawa, at an initial salary of $3,600 per annum, which will be increased upon recommendation for efficient service at the rate of $180 per annum, until a maximum of $4,500 has been reached.

Duties.—To supervise, under the direction of the Director of the Geological Survey, the field work of parties engaged in areal, structural, and stratigraphical surveys of one or more geographical or geological divisions of Canada; to conduct the instrumental surveys and mapping of the topography and geology of certain areas; to conduct the exploration, geological investigation, and detailed survey of mines and mining areas showing the structure of ore bodies; to conduct the making of collections of mineralogical, palaeontological, geological, and other specimens; to direct the preparation for publication of reports monographs, serial geological map sheets with structural sections, and papers embodying the results of field work; to supervise the collection, classification, correlation, and arrangements for ready reference of data regarding the mineral resources and geographical, petrographical, forest, and other economic or geological features of areas investigated; and to perform other related work as required.

Qualifications required.—Education equivalent to graduation in science from a recognized university, the attainment of a post-graduate degree from a university of recognized standing, and at least five years of experience in responsible charge of field exploration and geological research; intimate knowledge of Canadian geology, modern geological literature and museum methods, and the significance, scope, and economic importance of the work of the Geological Survey; demonstrated ability to address the public and to complete and publish the results of original investigation. In this case, preference will be given to candidates who have had a wide and varied experience in Geological Survey work. While a definite age limit has not been fixed for this competition, age may be a determining factor in making a selection.

The Mineral Province of Western Canada

Has produced Minerals valued as follows Placer Gold, $76,542,203; Lode Gold, $109,647,661; Silver, $59,814,266; Lead, $51,810,891; Copper, $170,723,242; Zinc, $24,625,839; Coal and Coke, $238,289,565; Building Stone, Brick Cement, etc., $36,605,942; Miscellaneous Minerals, $1,358,839; Making its mineral production to the end of 1922 show an

Aggregate Value of $734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive $94,547,241; for five years, 1896-1900, $57,605,967; for five years, 1901-1905, $96,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for 5 years 1915-1920, $189,922,725; 1921, $28,066,641; for the year 1922, $35,158,843.

Production During last ten years, $339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

VICTORIA, British Columbia.
THE HON. THE MINISTER OF MINES,

PROVINCE OF QUEBEC

MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

MINER'S CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONORABLE J. E. PERRAULT,

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

NO. 7 ANGLE CHECK VALVE, CHECK VALVE AND BRASS GLOBE VALVE

VALVE ENDURANCE TO CUT UPKEEP COSTS

Long life is built into every Crane check valve. Their renewable discs outlast others because the guides of special design confine wire drawing to the metal. True and accurate piping connections make them line up perfectly in an installation.

A complete line of Crane check valves is provided, for working pressures up to 2500 pounds. All are of tested strength and match the enduring quality of Crane equipment for every industrial piping and sanitation need.

MINES BRANCH

Recent Publications

Talc and Soapstone in Canada, by H. S. Spence.

Titanium, by A. H. A. Robinson.

Summary Report of Investigations made by the Mines Branch during the calendar year ending Dec. 31, 1921.

Phosphate in Canada, by H. S. Spence.

The Preparation, Transportation and Combustion of Powdered Coal, by John Blizard.

Road Materials along the St. Lawrence River, from Quebec Boundary to Cardinal, Ont., by R. H. Picher.

Barium and Strontium in Canada, by H. S. Spence.

The Coal-fields and Coal Industry of Eastern Canada, by F. W. Gray.

Analyses of Canadian Fuels. Part I to V, by E. Stansfield, M. Sc., and J. H. H. Nicolls, M. Sc.

Graphite, by H. S. Spence.

Gas Producer Trials with Alberta Coals, by J. Blizard and E. S. Malloch.

The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the developing of the general mining industry of Canada:—

Fuel Testing Laboratory.—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.

Ore-Dressing Laboratory.—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.

Chemical Laboratory — Analyzing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.

Ceramic Laboratory.—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.

Structural Materials Laboratory.—Experimental work on sands, cements and limes is also undertaken.

Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to The Director, Mines Branch, Department of Mines, Ottawa.

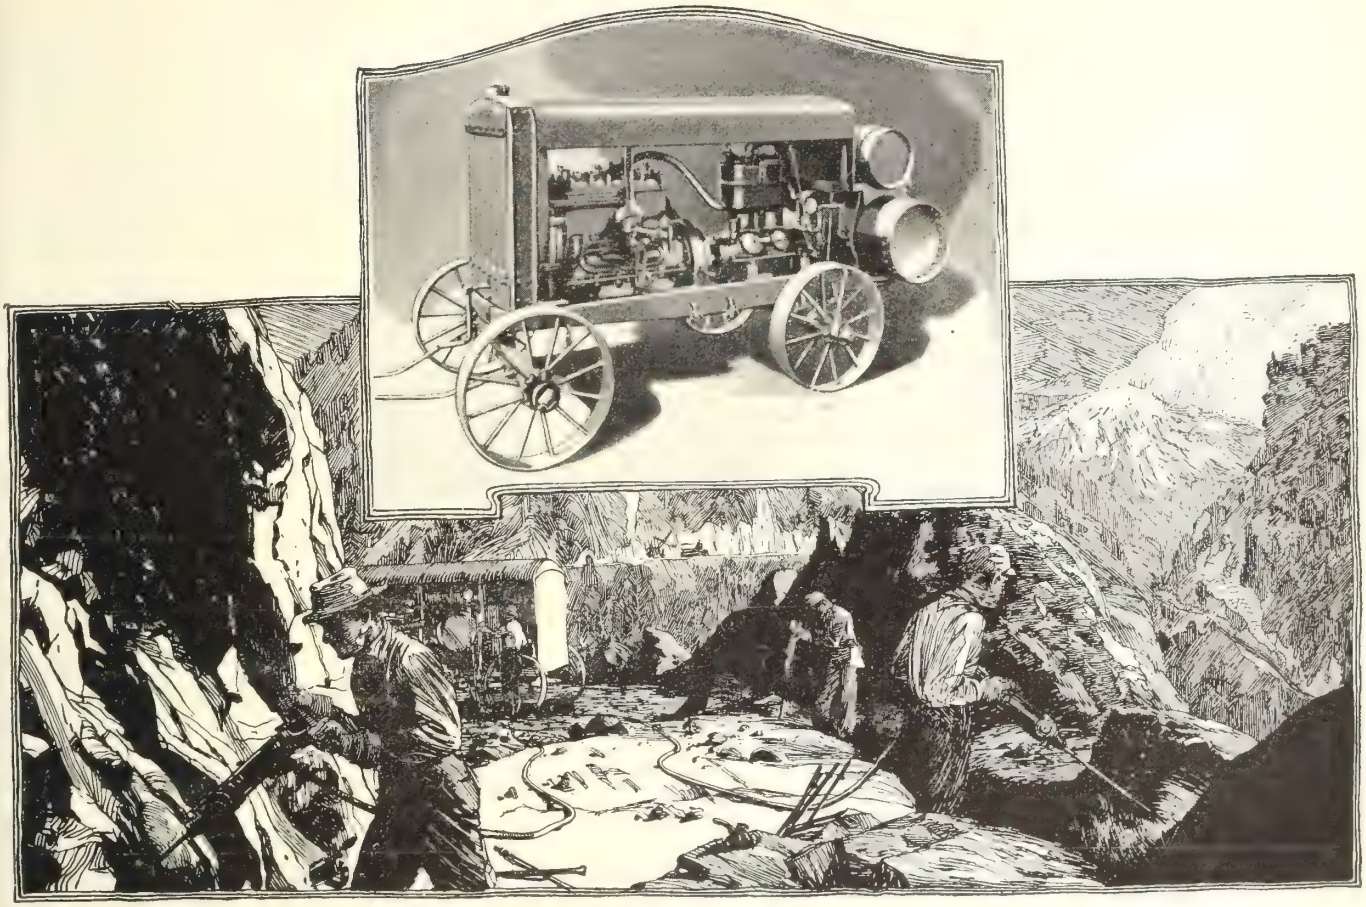
Applicants for publications not listed above should mention the precise area concerning which information is desired.

Summary Report — The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist's report is required, or what subject they are interested in.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

Communications should be addressed to The Director, Geological Survey, Ottawa.



For Development Work or Road Building PORTABLE COMPRESSORS

It is not always desirable to install a stationary steam or electric driven compressor plant for prospect or development work. With an Ingersoll-Rand steam or electric Portable Compressor you can get on the job quickly and easily and have the work well along before a stationary plant could be erected.

A well-known mining company recently used one of these machines for driving a tunnel and reported—"the compressor works with remarkable smoothness, ease and efficiency and with very little oversight."

For road building, trench work or rock removal over an extended area, Ingersoll-Rand Portable Compressors and one man "Jackhamer" drills are the acknowledged standard. The ease with which they can be moved about and operated, the freedom from heavy fuel haulage and erection makes these outfits the ideal portable rock drilling equipment.

Ingersoll-Rand Portable Compressors are complete, compact, self-contained air power plants. Compressor, tractor type gasoline engine (or electric motor), air receiver, cooling water system and accessories are mounted on a covered steel truck with removable side covers. Sizes 91, 160 and 210 cu. ft. per min.

Ask our Nearest branch office for complete information on Portable Compressors, Rock Drills and Drill Steel Sharpeners.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387
	Dividends.		

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

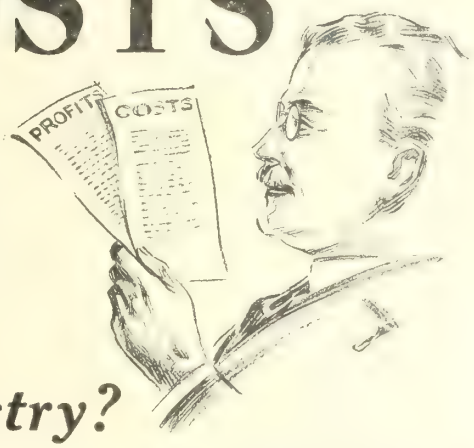
PROFITS *and* COSTS



Have you ever considered how much the figure on these significant sheets depend on

Chemistry?

PROGRESSIVE business men in all lines, looking beneath the surface for the fundamentals which influence success, are realizing that **chemistry** is the basis of all industry. How much more important it is then, for you who are in the chemical field — you who deal directly with chemicals, oils and paints— to be thoroughly familiar with new ideas regarding materials, processes and equipment for reducing costs, improving quality and promoting general efficiency. You can benefit immeasurably by attending the

NINTH

NATIONAL EXPOSITION *of* CHEMICAL INDUSTRIES

September 17th-22d, 1923

Grand Central Palace, New York

A chemical market paper said of last year 's Exposition:: "It is as comprehensive as an industrial encyclopedia. The products on view include types of everything of this group manufactured in the United States: coal, medicinals, dyestuffs, technical chemicals for rubber, leather, paper, textiles, paint and other consuming trades, finished products showing the results of treatment with these chemicals, and types of modern chemical equipment from the smallest to the largest. The Exposition is a liberal education in modern industrial chemistry."

In addition to being a vast "idea exchange" it is an impressive demonstration of how you can apply new processes, methods and devices in solving your own problems. You can spend several days profitably going through the exhibits on the four floors. Plan now to get the benefit of America's Most Important Industrial Exposition.

Write for details about this Exposition and how Chemistry plays such an important part in all industries

Assisting in the Development of the Mining Industry

It is essential that the peculiar banking needs of those engaged in the exploitation of Canada's natural resources be met with special facilities.

The Imperial Bank, ever a constructive element in the progress of Canada, long since realized the need for interested financial service to enable the proper development of the mining industry.

By opening branches throughout the mining districts and continually adding to them, as necessitated by expansion, this Bank has materially assisted in the development of the industry throughout Canada.

Those whose business is mining will find our facilities adequate and our knowledge of conditions valuable.

IMPERIAL BANK OF CANADA

For Economy Use Hercules Pine Oil

We are glad to co-operate with flotation operators to determine what oils will insure them the largest net earnings. The cheapest flotation reagent in the long run is the one which uniformly recovers the greatest amount of concentrate per ton of ore.

This the proper grade of Hercules Pine Oil will do.

Moreover, efficient flotation can be had only when every shipment of pine oil is uniform. We are prepared to furnish you with Hercules Pine Oil of unvarying quality produced under strict chemical control.

We offer gladly the experience of our technical service men in helping you solve your flotation problems.

QUEBEC GOLD REPORT PUBLISHED

The interim reports on the Opasatika and Duparquet map-areas, which cover the western part of the gold-field of northwestern Quebec, are now available in *Summary Report*, 1922, *Part D*, of the Geological Survey, Ottawa. Fortunately for those interested in developing the area, as well as for the usefulness of the data gathered by the field parties last summer, Dr. Cooke wrote summary accounts of the district, which were published in the *Canadian Mining Journal* on April 13th and May 25th. During the first week of June the maps of the two areas were ready for distribution in Ottawa, and by the end of the month that part of Dr. H. C. Cooke's report bearing more particularly on the economic problems was made available to the public in the 1922 report of the Bureau of Mines, Quebec.

The Summary Report was designed originally to make available to the public promptly after the close of the field season such interim reports and minor reports as it was deemed advisable to publish in such a form. It fails to serve that purpose at present; but it has other uses that are probably equally as important, and we judge there is plenty of warrant for continuing its publication as at present.

The need for the prompt publication of certain of the reports of the Federal Department of Mines, in both its branches, continues as before. The case cited above illustrates the need, and one expedient for meeting it. We understand that plans are afoot to bridge this obvious gap between the mining public and the technical officers of the Department of Mines, and we trust the public will have the benefit of some adequate provision immediately succeeding the present field season.

THE SOLUBILITY OF SULPHUR IN SLAGS

A notable research on the chemical reactions of the iron blast-furnace was recorded in a paper by Professors Richard S. McCaffery and Joseph F. Oesterle of the University of Wisconsin, presented on August 30th at the Montreal meeting of the American Institute of Mining and Metallurgical Engineers. These two teachers of metallurgy have in progress a series of experiments to determine, for the first time, the quantitative solubility of the sulphides of lime and manganese in the slags of various compositions commonly used in the blast-furnace, and the effect of temperature on this solubility. This investigation has long remained a pressing need, as one of the chief factors in converting blast-furnace practice from the empirical art it is today into the chemically controlled science we hope some day to make it. In this direction lie efficiency, enhanced profits and a lengthened life for the giant units of our iron and steel industry.

This present important advance in the knowledge of ferrous metallurgy is based essentially upon work at the Geophysical Laboratory in Washington by Rankin and Wright, who investigated thoroughly the characteristics of the ternary system lime-alumina-silica, which three oxides are the fundamental constituents of blast-furnace slag. In addition to this basic research, there is the work of Feild and Royster of the United States Bureau of Mines, whereby the temperature-viscosity relations of the whole range of blast-furnace slags were determined. With the results of these two outstanding investigations available, it has been a comparatively simple matter to measure the solubility of calcium sulphide and of manganese sulphide in a series of slag mixtures.

Typical blast-furnace slag has been shown to consist essentially of the three minerals anorthite ($CaO.Al_2O_3.2SiO_2$), calcium bisilicate ($CaO.SiO_2$) and gehlenite ($2CaO.Al_2O_3.SiO_2$). First the solubility of the two sulphides was determined in each of these three compounds throughout a range of temperature from the melting points up to 1,600° C. Then, by aid of the tri-axial diagrams of Rankin and Wright, new diagrams were prepared showing the solubility of the sulphides in any mixture of the three minerals — that is to say, in any ordinary blast-furnace slag.

There are two outstanding results of this investigation, which confirm and explain the observations and conclusions of furnace operators. First, at any definite temperature the slags of highest alumina content will dissolve most calcium sulphide, while those low in alumina will dissolve more manganese sulphide. "Because of the much greater solubility of sulphur when it is in the form of manganese sulphide than when calcium sulphide, it would be desirable to cause reactions forming manganese sulphide to take place in the blast-furnace. At the present time, however, the factors controlling this reaction are not known, but an attractive field for research to determine them is opened up." The tables given in the paper show that, particularly at high temperatures, manganese sulphide is more soluble than iron sulphide, reaching 90 per cent. and more of its weight in the slag at 1,600° C.

The second important point demonstrated by the experiments is that the solubility of the sulphides in slag of any composition increases rapidly with increased

temperature. For instance, "if the temperature of the slag is increased from 1,400° to 1,600° C., the solubility of calcium sulphide is increased about three times and the solubility of the manganese sulphide is increased about six times. The temperature is a much more important factor than the chemical composition in effecting the solubility of sulphur in the slag."

The practical importance of these considerations needs only to be mentioned to be realized by those familiar with the operation of the blast-furnace. If a comparatively small rise in the temperature in the hearth will allow the use of coke and ore higher in sulphur than than that at present used, the reduction in the cost thus attained might more than pay for the cost of the extra heat. It is practicable to attain to this higher temperature only by one means—an oxygenated blast. In this connection it is of interest to note the report from the United States Bureau of Mines, noticed on another page, which concludes that oxygen by the ton at a price that makes it available for purposes such as this is probable in the near future.

There is also the possibility of using oxygen from the electrolytic reduction of iron from ore to enrich the blast. A combined electrolytic and blast-furnace plant might prove to be an interesting and lucrative venture. The blast enriched with oxygen would give a gas of a much higher value for power purposes at the top of the furnace. This would augment greatly the present surplus of power available from blast-furnace gas, a large part of which might be made available as electric power via the gas engine. This cheap electric power could then be used advantageously to separate iron ore into its component parts, pure iron and oxygen. Thus the production of electrolytic iron would aid the operation of the blast-furnace, instead of competing with it.

This research of Messrs. McCaffery and Oesterle opens up some most interesting avenues, some leading to further research and others to improvements in and additions to the blast-furnace practice. It, as well as the preceding studies upon which it is based, are worth the closest attention of Canadian blast-furnace men.

THE PUBLIC PAYS THE PIPER

Once more the public will pay the cost of a strike settlement. The anthracite operators of the United States and the Union leaders have agreed upon a ten per cent. increase in wages and the universal adoption of the eight-hour day. Thus those in Canada who wish to heat their houses during the coming winter with Pennsylvania anthracite will find plenty of it available—at an enhanced price.

Already coal dealers in Canada have made it known that the addition to the miners' wages and the subtraction from their hours of labour will be charged up to their customers. Governor Pinchot, whose plan of compromise has settled the strike, states that he hopes to conduct a public investigation whereby a reduction in freight rates and in the profits of wholesalers, brokers, jobbers and retailers will absorb the difference. We are not hopeful of his success in this direction; and at any rate, it could have little effect in this country, where another set of "coal barons" hold sway.

It is a noteworthy fact that the chief provisions of Governor Pinchot's proposal, now accepted, involve added costs of mining, which can be passed on readily to the public. The operators have continued steadfastly in their refusal to allow the "check-off", which they consider, no doubt rightly, would put them hopelessly in the power of the labour union.

The lesson for us Canadians is plain to read. There are alternative sources of domestic fuel available to the householders of central Canada. We must see to it that they are developed to the utmost. The efficacy of fuel controllers and public boards in controlling prices is limited and their awards are not final, as we have seen recently. We have also seen lately that competition in supply is the surest and best means of reducing prices to a reasonable figure. If each and all will examine shrewdly the alternatives to American hard coal and will purchase the best and cheapest fuel, we shall cease soon to pay our present huge annual tribute to those who provide us with Pennsylvania anthracite.

IRON ORE SUPPLY

Iron ore mining at Wabana in Newfoundland was curtailed seriously last week. Last year an outlet for 600,000 tons of ore during 1923 was arranged with German companies in the Ruhr district. Most of the furnaces there are now out of blast and the orders have been cancelled. A limited number of cargoes are being shipped to Philadelphia, and a few cargoes have been contracted for in England, where it is hoped there may be found a good market for the ore of Wabana. Meantime there is distressing unemployment among the iron ore miners of our sister Dominion.

In Ontario we find a different phase of the same problem. The vast deposits of iron ore that have been investigated to date are not acceptable to the furnace managers in their natural state, and the attempts to beneficiate them, though technically feasible, have been commercially unsuccessful. So close to success have two of the attempts come, however, that they are sure to be put to use within a short term of years. The report of the Committee on Iron Ore, appointed a year ago by the Ontario Government has not yet been made public officially; but it is understood to include a recommendation that a bounty be paid to the miners of native iron ore to help them "over the hump", with a view to independent and profitable operation when the bounty shall have expired. When this has been effected, Ontario, like Newfoundland, will find herself in possession of merchantable iron ore much in excess of the markets available, and the

province's present case of utter dependence upon imported ore will be altered to a capacity to export ore limited only by the opportunities for its sale.

Reports of the iron ore survey in progress in British Columbia indicate that there, too, the problem is to find a market. Much of the ore is of good quality, is readily accessible both for mining and for transportation and is held by owners anxious to dispose of it at reasonable rates. The only problem of consequence is as to whether the small and scattered population of the province, added to its opportunities for the export of iron and steel, warrants the erection of a modern iron and steel plant.

In Alberta, on the other hand, there is as yet no discovered iron ore. It is up to the prospector to find adequate supplies of this basic industrial material in that part of Canada whose fuel resources, it is confidently stated, will make it eventually the industrial centre of the Dominion. We cannot predict what the prospector will find; we can only hope.

The time is not far distant when, on the Pacific coast and on the Great Lakes, Canada's supply of iron and steel will be derived from her own ore. Though Newfoundland has not found it expedient to join our confederation, she will, doubtless, always make the Wabana ore available on preferred terms to the owners in Nova Scotia. Thus the outlook for the supply of iron ore for Canadian furnaces is bright, if we look well ahead. The increase of population on the Pacific coast soon will warrant the establishment of an iron and steel plant. By hook or by crook (signifying in this case a bounty) we must establish firmly the use of beneficiated ore in Ontario. The difficulties besetting the iron and steel industry in Nova Scotia (mainly financial and managerial) are being overcome rapidly by the present consolidated control, and the future is more promising than ever before.

AN APPALLING DISASTER

The fearful earthquake disaster that has overtaken the Tokio and Yokohama district of Japan is not only appalling in its tragic and terrible character, but also bewildering in its magnitude. At this writing, the death list is placed at over 300,000.

Numberless persons are homeless and destitute and terror, disorder and misery are rampant on every side. To this greatest disaster in the history of the world a typhoon contributed the final touch of horror. Missionary circles in Canada, as in other countries, are naturally plunged in the deepest concern and dismay, as a larger number of missionaries were known to be stationed in the regions affected.

This terrible disaster has called forth the world's sympathy for Japan in literally unstinted measure. Already help of the most practical kind is being given to the afflicted country, and there looks no doubt that whatever material assistance can be subsequently rendered in repairing the damage wrought by the holocaust, so far as it is capable of being repaired, will be freely and gladly given. But it seems undoubted that so sudden and so heavy a blow must mean a substantial check to the progress and prosperity of Japan.

The world at large is getting to know a good deal more about Japan than it used to do, and with knowledge have come increased and increasing understanding and appreciation. The Japanese are the most patriotic of peoples, and it is this patriotism of theirs that has, before now, brought them steadfastness and unity in times of storm and stress. The war with Russia first disclosed their possession of naval and military genius of a high order. They are at once skilful as strategists and courageous as combatants. And it would ill become those who dwell in any part of the British Empire to be forgetful of their fidelity to their friendship with Great Britain during the Great War. They are a kindly, helpful, hospitable, industrious and highly intelligent people — a people who are bound to occupy a position of increasing influence and importance among the nations of the earth. In days to come, one may be sure, they will not forget the sympathy and help extended to them in their present hour of national calamity.

RESEARCH AND WAR'S BURDENS

In order to maintain current standards of living and culture in the face of burdens left by the war, it is imperative that industrial development in future be definitely assured. Since manufacturing advances are won by the introduction into industry of new knowledge, it follows that new knowledge must be systematically sought, and that a portion of the product of industry must be set aside for pursuing the means of further progress.

On the personal side, it calls no less for the proper technical and social education of all grades of workers, together with the fullest utilization of their powers in modern administrative systems affording the most effective co-ordination of personnel.

The organization necessary to meet the two requirements thus broadly distinguished as research and education will be an integral part of the newer type of industrial administration, and the exercise of these functions will provide solutions to many pressing industrial problems. — From "Research in Industry," by Fleming & Pearce.

GOLD IN TANGANYIKA

One of the administrative officials of Tanganyika Territory recently described the minerals of this former German colony before the Royal Colonial Institute in London. Prominent among these is gold, found in quartz veins in the Mwanga district, southeast of Victoria Nyanza. The Germans had succeeded in developing one paying mine there, in spite of the isolated situation, and others were in the prospect stage. It is expected that the area will become an important producer of gold.

Canadian Mining Men

D. H. MacDougall

Donald Hugh MacDougall, Vice President of the British Empire Steel Corporation, was born in Cape Breton in 1879. He attended the public schools until he was thirteen and left then to begin work. He continued to study, however, and attended the Government Mining Schools. He took courses in the International Correspondence Schools and the Dalhousie Summer School (Mining Course). For a year or so he was an apprentice mechanic. He became, in turn, Assistant Mine and Railway Surveyor; Mine Surveyor; Mining Engineer; Civil Engineer and Engineer in charge of Construction, for the Dominion Iron and Steel Company.

Mr. D. H. MACDOUGALL

From 1902 to 1904 he was Assistant Resident Engineer on the New York Central and Hudson River Railway; from 1904 to 1907, Manager of the Wabana Iron Ore Mines, Newfoundland; in 1907, Superintendent of Mines and Quarries, Dominion Iron & Steel Company. In 1910 he was made Assistant General Manager of the Dominion Coal Company, becoming General Manager two years later. In 1916 he was appointed General Manager of the Dominion Iron & Steel Company.

In 1918 Mr. MacDougall became President of the Nova Scotia Steel & Coal Company; and when two years later the British Empire Steel Corporation was organized he was elected Vice-President. This was a fitting recognition of his efforts in bringing together into one organization the two largest companies of the Province, whose interests were being injured by separate management and whose whole future was jeopardized by boundary disputes. A wide experience gained in the Wabana iron ore mines and in the coal mines of both companies had taught Mr. MacDougall the utter folly of continuing to operate two large concerns on the same properties, so divided that access could be attained separately only by enormous expenditures. After all was said and done, outputs were low, costs were high, and a critical and dissatisfied public hurled deadly shafts of censure against the unbusiness-like methods of the two large companies. His keen eye was quick to see that waste must be eliminated and economy practised everywhere if success was to be attained. Temporary policies of operating the mines, both ore and coal, must be superseded by far-sighted business methods, with plans for the distant future, and not merely for a day. Great industrial problems confronted the coal industry, which would be reflected in the steel trade and required the leadership of great minds. The first thing to be done was to consolidate the two companies, meet the problem squarely, and then bend all the combined energies and resources on a solution.

Once this was agreed to (and Mr. MacDougall played a large part in bringing the warring factions into accord), the work of organization speedily followed. To appraise the values of the Wabana ore mines and of the plants and collieries of the Dominion and Scotia companies was not a difficult task. The ore deposits of Wabana and the coal seams of Cape Breton had never been fully valued, much less the Acadia coal field in Pictou county with their phenomenally thick seams. Now their value has been greatly enhanced under the care of a Corporation able to employ the best mining engineers and ready to provide the best colliery equipment and facilities for transportation to markets, near or far.

While doing his part in this great work, Mr. MacDougall has not neglected the other activities of a well-rounded life. He is a good friend, a good neighbor and a good citizen, as well as one of the leaders in his profession in Canada.

THE JOHNS-MANVILLE ASBESTOS FACTORY

One of the important industrial developments of the day is the establishment by the Canadian Johns-Manville Co., Limited, of a plant for the manufacture in Canada of asbestos products. The undertaking is of special interest because it represents a new venture in the manufacture of asbestos products on a large scale in Canada.

The plant is being erected at Asbestos, Quebec, right where the asbestos is being mined. This will help materially in keeping down costs, since freight charges will be eliminated and the savings effected should prove beneficial to the Canadian consumer.

At present two buildings are being constructed. These are one-story concrete and steel structures, 1,000 x 150 feet, and costing approximately $250,000. It is expected they will be completed and ready for use in time to admit of delivery of manufactured products on or before January 1.

The following lines will be turned out: asbestos roofings, shingles, packings, building materials of all kinds, insulation, paper and millboard, brake linings, etc. The initial installation will be sufficient to take care of all Canadian requirements.

Natural Gas and Petroleum Resources of Western Canada

The Recovery of Natural Gasoline by the Compression and Oil Absorption Methods

By NEWTON W. EMMENS

Transmission of Natural Gas for Heating and Power

From what work has actually been done, and from the knowledge we have of the geological formation and structure, it can be stated that in east central Alberta and in northwest Alberta there are natural gas resources that can be made of great utility and commercial importance to both the Province of Alberta and the Dominion, provided this gas be utilized and is not either shut in the ground or wasted in the air. It is admitted, of course, that the ideal way to utilize natural gas is for domestic heating, lighting and cooking, and as a fuel in the development of power for manufacturing plants, or as the motive power, when used in gas engines, for the same purpose. Before gas can be thus utilized, however, there must exist both the population and the manufacturing plants within a reasonable distance of the gas field to consume sufficient gas and pay a price high enough to warrant the operation of the field and the investment requisite to the laying of the pipe-line from the field to the centre of population.

What constitutes a reasonable distance from the field to the place where the gas is to be used depends upon the quantity of gas used daily and the pressure of the gas at the field end of the pipe-line. If the distance be 100 miles and the pipe be 8 inches in diameter with a pressure of 200 pounds per square inch at the field end, it would deliver 4,273,000 cubic feet of gas per day at the other end against a pressure in the distributing mains of 5 pounds, or 4,217,000 cubic feet against a pressure of 25 pounds. If the pressure were 100 pounds per square inch at the field end of the line the amount delivered would be 2,261,000 cubic feet per day against 5 pounds pressure and 2,185,000 cubic feet against 20 pounds. If this pipe line were 6 inches instead of 8 inches the quantity of gas delivered at the end of the 100 miles would be 2,050,000 cubic feet per day with a 200 pound pressure at the field end of the line and 5 pounds at the discharge end, and only 1,084,000 if the pressure were reduced to 100 pounds at the field end.

Size of Community Required

The quantity of gas used by the average consumer is 80 cubic feet per day (Indianapolis, U. S. A.) to 200 cubic feet (Kansas City). The amount of natural gas required for manufacturing is:—

Brick-making — 15,600 cubic feet per thousand brick.

Generation of electricity with steam installation using the gas as fuel under the boilers, takes 40 cubic feet per kilowatt hour. If an efficient type of gas engine is used to drive the generator it will take about 18 feet per kilowatt hour.

Steam engines, where the gas is used as fuel under the boilers, will take more or less gas according to the efficiency of the engine. A triple expansion condensing engine requires 16 cubic feet per horsepower-hour, while a single cylinder, cut-off engine requires 40 cubic feet per horsepower-hour.

A gas engine of the most efficient type requires 9 cubic feet per horsepower-hour, while a small ordinary gas engine will take 13 cubic feet per horsepower-hour.

If we take these figures and assume that the average amount of gas consumed for heating, lighting and cooking is 150 feet per day (which is high) throughout the year for each consumer, that is per family, in some Alberta town, and if we assume that this same town develops 2,000 horsepower for twelve hours each day for its factories, and 10,000 kilowatt-hours of electricity, it will require 22,000 consumers, or a population of over 100,000 to take care of the 4,273,000 cubic feet of gas.

A gas well having an open flow of 5,000,000 cubic feet of gas per day, with a closed rock pressure of 500 pounds per square inch, will deliver into a pipe line against a pressure of 200 pounds 2,915,000 cubic feet per day, so that two such wells would supply the gas required for our supposed town. If the wells only had a closed pressure of 300 pounds and an open flow of 2,000,000 cubic feet it would take eleven wells, which is a small number for a gas field.

The Uses for Alberta Gas

In that part the Province of Alberta referred to in a former article (C. M. J. August 24th, p. 665) there are four gas fields where development has proceeded far enough to assure a large supply of gas and to call for the consideration of its utilization. These are the Peace River, Pelican, Viking and Irma-Wainwright fields, of which only the Viking field is within reasonable distance of a city of sufficient size to warrant the capital expenditure in laying a gas line and supplying gas to it. This is the city of Edmonton and a pipe line is now being laid from the Viking field, a distance of 78 miles.

There is no town of any size within a radius of 100 miles of the Peace River, Pelican or Irma-Wainwright fields and there is no market for the gas as such. If, therefore, the gas is to be utilized and some return made to those who expend their capital in the developing of the fields, it is necessary to utilize the gas by manufacturing from it commodities that are necessary in the commercial activities of the nation and for which there is a continuous demand. Chief among these are gasoline and carbon-black.

What natural gas is and how gasoline occurs in it were explained in my last article (C. M. J. August 24th, pp. 665-667). I propose now to describe the several processes for its commercial recovery, leaving the matter of carbon-black manufacture from natural gas and its uses in the arts for another time.

Recovery of Gasoline by Compression of Gas

The first commercial use of gasoline obtained from natural gas appears to have been in the year 1904, when operators near Titusville, Pennsylvania, collected the condensate from their gas mains and sold it for use in gasoline engines. In 1905 the yield of gasoline thus obtained was increased by chilling the pipes carrying the gas with water, and experiments were commenced to develop some mechanical process whereby this gasoline could be extracted from the gas at the wells, before it entered the pipe lines. These experiments were successful and between 1905 and 1909 several plants were erected in the oil fields to recover the gasoline from the

rich casing-head gas by means of single stage, low pressure compressors. Since that time many improvements have been made in the methods of recovery by compression and the percentage of recovery has been increased greatly.

Prior to 1904 the liquid that condensed in the gas pipe-lines and accumulated in the low places was regarded as a nuisance, because it interfered with the steady flow of the gas, and because it necessitated the employment of men to go over the lines at intervals and drain this condensate from the low places, thus adding to the expense of operation. No one then realized that in a few years' time this liquid would become an important article of commerce and would add millions of dollars to the income of the natural gas producers throughout the country.

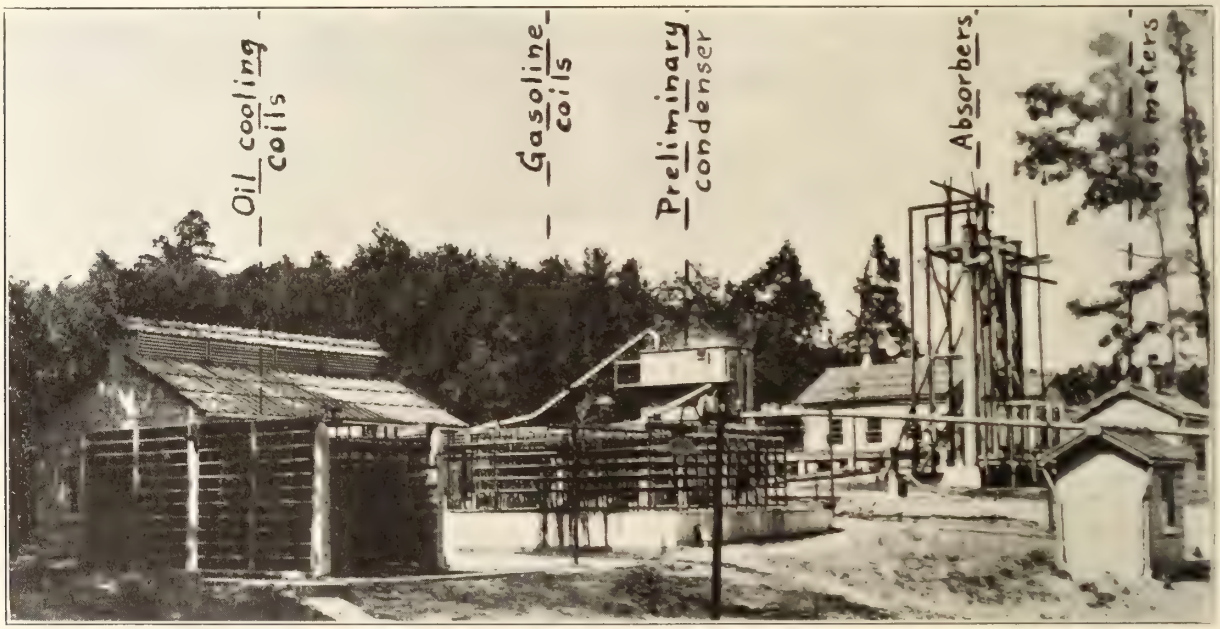
Laws Governing the Operation

The theory of the precipitation of gasoline vapors from natural gas may be compared with that of the precipitation of moisture from the atmosphere. Water vapor exists in the air at all times, in varying proportions, but is invisible unless condensed by cooling. Cooling alone, unless carried to an extremely low point, does not extract all the moisture from air, but if we take this cooled air and compress it, so as to reduce its volume several fold, we can extract another part of the water from it. It is seen, therefore, that we can extract water from the air either by cooling it or by compressing it, and if we use a combination of these processes we can make the maximum extraction.

The condensable vapors in natural gas are invisible under ordinary conditions, but at times the sudden release of natural gas under high pressure into the atmosphere will cause these vapors to condense and form a mist or fog, due to the sudden drop in temperature caused by the expansion of the gas.

In the extraction of gasoline from natural gas the desired result could be obtained either by reduction of pressure or by cooling, if it were not for the complex mixture of the gases, each of which has a different liquefaction temperature and pressure. Consequently without an exact knowledge of the proportion of each member constituting the gas to be treated any attempt to calculate the most suitable pressures or temperatures to precipitate them is little better than a guess, and the only practical method of arriving at the desired information is by actual tests and experiments.

According to the law of partial pressures, a gas containing 10 per cent of condensable vapor and under a pressure of 100 pounds would have acting upon the condensable portion a pressure of only 10 pounds, or 10 per cent of the total pressure. As the proportion of the condensable vapor in the gas becomes less through condensation, the partial pressure acting upon the remainder also becomes less until the point is reached where such pressure is too small to cause any further precipitation, thus leaving a part of the condensable vapors still in the gas. If, however, at the same time that the gas is being compressed its temperature be lowered by cooling, more of the vapors will be condensed and a higher percentage of recovery made. If the pressure be carried high enough and the compressed gas be cooled sufficiently it is possible to liquify, not only the vapors but every part of the gas; but such pressures and temperatures are not commercially practical, as the machinery required to attain them would be too expensive to install and operate. Commercial considerations, therefore, require that the pressures and temperatures employed be such as can be obtained by the use of standard machines, pipes and fittings, which will recover the largest possible amount of condensate that will conform to the standards of safety and make a good motor fuel.



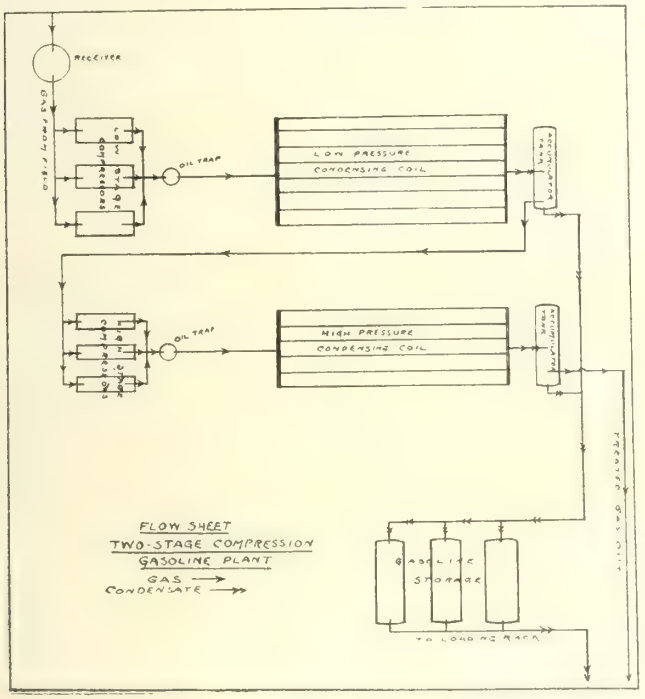
Oil Absorption Plant for Natural Gas

Portable Experimental Plant

Not only is the natural gas from each field of a different analysis, but the gas from each producing sand, and often from each individual well, contains a different proportion of the several hydrocarbon gases. It is necessary, therefore, to test the gas under different pressures and temperatures with an apparatus that as nearly as possible duplicates the proposed plant operations and conditions, in order to obtain the requisite data upon which to design the plant. The first step in the process is to measure and test the gas from each well by means of a small portable apparatus, to arrive at the approximate gasoline content of the gas and to eliminate such wells as do not give off gas containing over one gallon of gasoline per thousand cubic feet. Having decided that there is a sufficient volume of gas rich enough in gasoline content to make its recovery

by the compression method a commercially profitable undertaking, the next step is to carry out the compression and cooling tests of the gas to be passed through the plant. The apparatus used in making these tests consists of a 10-horsepower gas engine, a small two-stage compressor, coils for cooling the compressed gas and condensing the gasoline, a tank for separating the condensate from the residue gas, two meters, one to measure the gas it comes from the field and the other to measure the gas after the gasoline is removed, and the various valves, connections, pressure gauges, safety valves, expansion valves, etc., necessary to connect the different parts of the equipment. The whole of this apparatus is mounted on a wheeled truck that can be hauled from place to place.

In making the test several measured quantities of gas are passed through at pressures up to 300 pounds per square inch, and the gasoline obtained carefully measured and its specific gravity taken after each run. Great care must be observed in taking the several read-



ings because of the small amount of gas handled at each test. Any error in observation or calculation when making the tests would be greatly magnified when applied to a plant operating on a commercial scale. It is inadvisable to make a condensate having a specific gravity of over 90 degrees Baumé, because of its excessive volatility, and an allowance of 25 per cent should be made for vaporization losses between the amount of liquid as shown by the tests and what will be actually marketed from the big plant.

The Compression Plant

A typical compression plant consists of two-stage gas compressors either direct connected to the gas engines that operate them or driven by independent gas engines with belt-drive, cooling coils, accumulator tanks, oil traps, storage tanks, blending tanks, water circulating pumps, valves, pipe-lines, fittings, gauges, and regulating devices, complete electric lighting system, steam heating system for entire plant, chemical fire-fighting equipment, with all necessary buildings. In addition, in places that are remote from centres of population, such as in central and northern Alberta, a well fitted pipe, machine, and blacksmith shop would have to be provided where all necessary repairs could be made. From the storage tanks a pipe-line is laid to the railway siding where the loading-rack is built and where the gasoline is loaded into tank cars for shipment.

The operation of the plant (see Fig. 1.) is as follows: The gas as it comes in from the field passes through a receiver where any dirt, water or oil being mechanically carried along by the fast moving gas in the pipe-line can settle. From the receiver the gas passes to the suction side of the low-stage compressor and is raised to a pressure of from 40 to 80 pounds. The discharge from this low-stage machine passes through an oil trap, where any oil that may have been taken up by the gas from the compression cylinder is separated, thence to a set of cooling coils where the first condensation takes place.

The gas then returns to the intake side of the high-pressure machine and is compressed up to 200 to 300 pounds. From here it passes through another oil trap and then on to the high-pressure condensing coils where the balance of the condensable vapors are precipitated, after which the gas goes into the pipe lines that lead it away.

The gasoline condensed in the low and high-pressure coils goes to the accumulator tanks, where any water that may have separated from the gas is collected and run off. From the accumulator tanks the gasoline goes to the storage tanks, or if its gravity be too high it is sent to the blending tank where enough naphtha is added to it to bring its gravity down to the required point. The cooling coils are cooled by a water spray that is kept continually playing on them, the cooling effect of which is increased by the evaporation of the water on the coils.

Treatment of Gas by Oil Absorption

The compression system of recovering gasoline from natural gas was originally considered to be efficient; but recent investigations have disclosed the fact that the percentage of extraction is quite low and that the residual gas contains from three-tenths to as high as eight-tenths gallons per thousand cubic feet, the recoveries being from 70 to 80 per cent on gas containing from 2 to 10 gallons of gasoline per thousand cubic feet. This system is applicable only to gas containing over one gallon of gasoline per thousand cubic feet.

There are a great many millions of cubic feet of natural gas produced daily that do not contain a sufficient amount of gasoline to make their treatment by the compression method commercially profitable. Investigations and experiments were carried out, therefore, to devise some process by which this could be done, taking as a basis the methods used in the recovery of benzol, toluol, and other products made from the distillation of coal, which consists essentially in causing the gas to pass through some medium that has the property of absorbing those portions it is desired to recover, which in the case of natural gas is the gasoline hydrocarbons.

Original Plant in West Virginia

In 1911 an experimental plant was erected at Hastings, West Virginia, and in 1913 the first large scale plant was put in operation at that place, under the direction of G. M. Saybolt, (by whom the process was patented), to recover the gasoline from the natural gas being furnished to the city of Pittsburgh, Pa., from the West Virginia fields. The process used consisted in causing the natural gas to bubble up through a petroleum distillate with a gravity of about 35 degrees Baumé, at a high pressure. The charged distillate then was

sent to a still where the absorbed gasoline was driven off and condensed, and the oil used over again. Since that time numerous improvements have been made in the details of the process, though the principal involved remains the same.

In this connection it is interesting to note that Saybolt is not the originator of the idea of recovering hydrocarbon vapors by absorbing them in oil, even though he was the first to put it into commercial operation. In 1875 a patent was granted to an Englishman named William Young, covering the process of absorbing the hydrocarbon vapors contained in gas by passing it counter current to oil and then distilling the charged oil to recover these absorbed vapors, and the apparatus described in that patent is very similar to that in use today, while the process described is identical. Unfortunately for Mr. Young he was before his time and before the days of the gasoline engine.

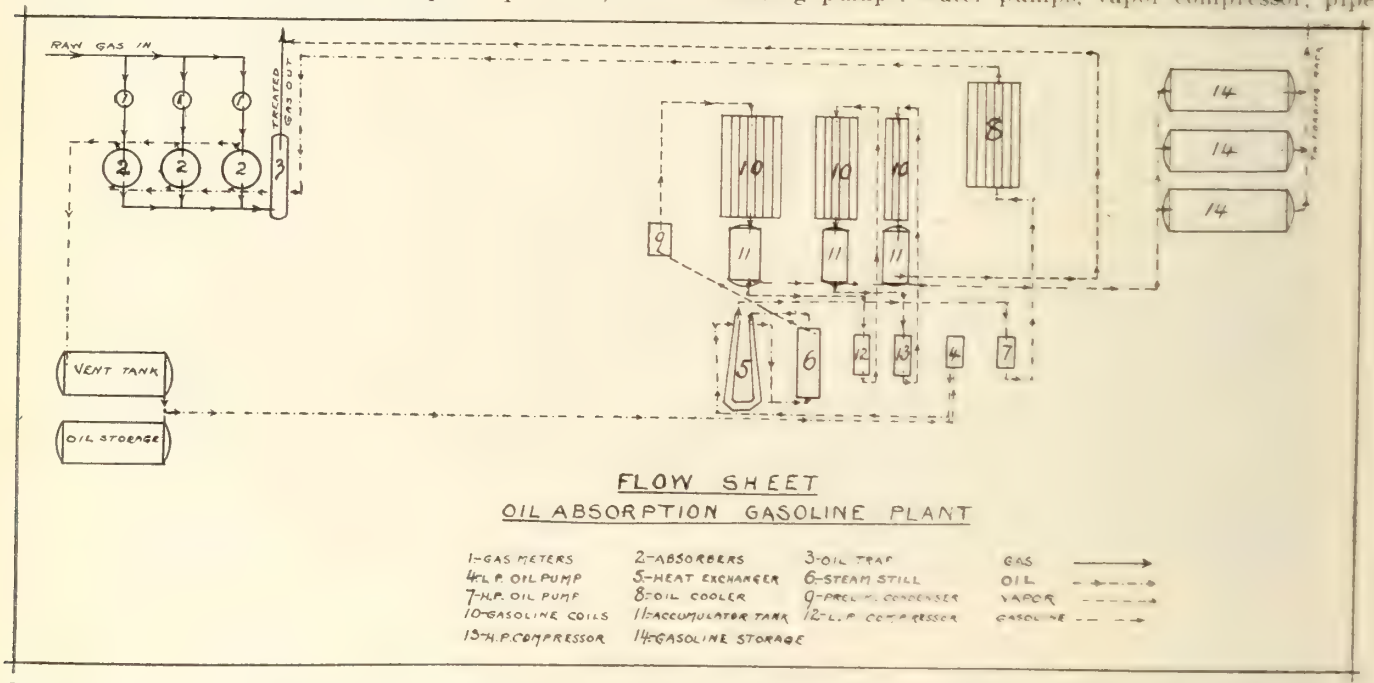
Natural gas follows Henry's law of gases, which states "The weight of any gas absorbed in the unit volume of liquid, at any pressure, will be equal to the weight absorbed in that volume at one atmosphere pressure, times that pressure (in atmospheres)". This law, together with that of partial pressures previously referred to, has an important bearing on the absorption process and its operation, but cannot be applied mathematically to plant designing, except in a very general way, because it is impossible to learn by any known method the percentages of the different hydrocarbons that constitute the gas, and therefore the pressure, temperature, and oil circulation per thousand cubic feet of gas that will yield the maximum commercial results. Such being the case, it is highly desirable that tests be made of the gas to be treated as nearly as possible under plant conditions, using the same absorption medium and making a series of runs at different pressures, with careful observations of the temperatures.

Experimental Plant for Tests

The apparatus used in making such tests consists of a small gas-compressor and engine to drive it, cooling coils to remove the heat of compression from the gas, gas-meter, and the absorber in which the gas is brought into intimate contact with the absorption medium, usually mineral seal oil, having a gravity of 35 to 40 degrees Baumé. The absorber consists of five absorption chambers connected in series, in each of which a definite amount of absorption oil is placed — usually 2,700 c.c. A measured quantity of the gas to be tested is passed through the apparatus at speeds varying from 20 to 400 feet per hour, depending upon the pressure at which the test is being made, — the higher the pressure the greater the permissible speed of the gas, the pressure depending upon the estimated gasoline content of the gas as determined by a preliminary examination. After the run the oil is drawn off from the absorption chambers and distilled, and from the gasoline recovered the content of the gas is arrived at. By making a series of tests under varying pressure, temperature and oil circulation conditions, the data are obtained upon which to design the full size plant in order to obtain the maximum commercial recovery.

Oil Absorption Plant

The large plant (see Fig. 2) consists of meters for measuring the gas, absorbers, heat exchangers, still, cooling coil, condensing coils, accumulator tanks, oil storage tank, vent tank, gasoline storage tanks, oil circulating pumps, water pumps, vapor compressor, pipes and connections, valves, and regulating devices. In addition there are the steam boilers, electric-light generating plant, pipe-fitting and work shop, laboratory, chemical fire extinguishers, and buildings to house the machinery. In some plants, where the field gas pressure is not high enough, there are added gas compressors.



The operation of the plant is as follows: The gas as it comes from the field passes through the meters, thence through the absorbers, from there to an expansion tank or oil trap to recover any absorption oil that may have been carried over mechanically by the gas, and then on to the discharge line out of the plant. In passing through the absorbers the gas enters at the bottom and out at the top. The absorbing oil is pumped from the still through the heat exchanger and the cooling coils into the top of the absorbers, out at the bottom, into the vent tank, whence it goes to the still and then commences the cycle again. In passing through the absorber from top to bottom the oil comes in contact with the gas going in the other direction, and takes up any gasoline vapors it may contain. In the vent tank the oil is allowed to settle for a short time, allowing it to give up any gas or light hydrocarbon fractions that

may have been carried over with it and that cannot be condensed. From the vent tank the charged oil passes through the heat exchanger, counter current to the hot distilled oil coming from the still, absorbing from the latter a considerable proportion of its heat, and then on to the still where its temperature is raised to about 210 deg. F. by means of steam and the gasoline driven off in the form of heated vapor. The oil, after having its burden of gasoline removed, goes through the heat exchanger, as already stated, and to the cooling coils where its temperature is reduced by means of a water spray playing on the outside of the coils, and from there to the absorbers again for a fresh charge of gasoline.

The vapor from the still goes first to a preliminary condenser where its temperature is reduced to 185 deg. F. and where any water or oil vapors it may contain are separated out. From here it goes to a set of water-cooled coils where the bulk of the gasoline is condensed at atmospheric pressure. All the gasoline hydrocarbons are not, however condensed in this first cooling coil (due to the law of partial pressure as previously explained), so the uncondensed vapors are taken to the vapor-compressor where they are raised to a pressure of 50 pounds per square inch, thence to a second set of cooling coils, where they give up another lot of gasoline, whence they return to the high side of the vapor-compressor and are compressed to a pressure of 250 pounds per square inch. After this final compressing they are again cooled in a third set of coils, and the balance of the liquifiable hydrocarbons recovered. Any vapors still remaining uncondensed are led off and mixed with the treated gas from the absorbers.

The gasoline recovered from each set of cooling coils differs greatly in both its gravity and quantity. The first set of coils yields a gasoline with a gravity of 72 deg. to 80 deg. B. and comprises from 50 to 70 per cent of the plant's output. The second set of coils gives a gasoline of 80 deg. to 90 deg. B. comprising 10 to 30 per cent of the output, and that from the last set of coils has a gravity of 85 deg. to 95 deg. B. and constitutes the balance of the plant's output. Owing to the high gravity and extreme volatility of this last gasoline it is good practice to mix it with low gravity naphtha and thus avoid excessive losses by volatilization in the storage tanks. It is also good policy to maintain a pressure of from 5 to 10 pounds on the gasoline in the storage tanks for the same purpose.

In treating natural gas by the oil absorption method it is better to do so under comparatively high pressures because the oil saturation with gasoline vapors may be carried to a higher point, which means a lessened oil circulation per thousand cubic feet of gas treated and a smaller quantity of oil to be handled through the still and oil circulation system. The recoveries by this process in a properly designed and carefully operated plant are from 87 to 95 per cent on the gasoline contained in the gas.

The next article will describe the treatment of natural gas by the charcoal process.

DISPOSITION OF SOUTH AFRICAN GOLD

"The Times" London, points out that for the first half of 1923 South Africa's gold was sent, 60 per cent. to India, 25 per cent. to New York, and 14 per cent. to continental European purchasers. All this South African gold was sold in London, and though this is no longer required by law, it seems likely London will remain the sole market.

CHEAP OXYGEN FOR METALLURGICAL USES

Revolutionary changes in the metallurgy of iron by which production costs should be materially decreased and quantities of low-grade ore and smelting fuels now considered worthless be made available as the result of the use of oxygen and oxygenated air in blast furnace practice are suggested in a report just made by a committee appointed by the United States Bureau of Mines to study the problem.

In the past it has been necessary in the production of one ton of pig iron to pass three tons of inert nitrogen through the blast furnace, resulting in serious heat and metal losses. The elimination of such losses by the substitution of oxygen, or a mixture of oxygen and air, has long been considered, but has not been put into practice on account of the inability to produce oxygen in quantities at sufficiently low cost to make such application industrially possible.

In view of the many recent developments in oxygen manufacture, and considering the increasing cost and decreasing quality of the nation's' raw materials, the Bureau of Mines appointed an advisory committee to study the problem of the application of oxygen or oxygenated air to metallurgical and allied processes. M. H. Roberts, of New York, is chairman of the committee.

This committee has made a thorough survey of the existing processes for the manufacture of 99 per cent. oxygen. The conclusions reached are that the comparatively small demand for the product has prevented the installation of large units suitable for metallurgical processes, with corresponding economies, and that by far the greater proportion of the present cost of oxygen represents the cost of transportation, storage and service. Large oxygen manufacturing plants can be built to serve metallurgical purposes directly, which will be capable of delivering oxygen at a cost not to exceed $3 per gross ton. In brief, the committee finds that the oxygen industry is now able to make plants for supplying large quantities of oxygen to metallurgical industries at low cost.

The data collected by the Bureau of Mines committee indicate that the production and utilization of cheap oxygen should also accomplish great economies in the metallurgy of zinc. It is believed that similar economies can be effected in the metallurgy of copper, and in fact in all branches of non-ferrous metallurgy. Great possibilities are pointed out in the application of oxygen in the manufacture of artificial gas and for various other industrial uses. The findings of the committee on these theoretical studies are of such revolutionary character that the members feel the strong advisability of conducting experimental work to verify the truth thereof, as well as to make changes in furnace design and processes in order to take full advantage of the probable benefits to be gained.

The committee has developed plans for experimentally determining the effects of oxygen enriched air upon the operation of the blast furnace, and it is recommended that these plans be put into effect as the first step of an extended research as to the general applicability of oxygen to metallurgy.

The knowledge that German industrial concerns are working actively on the application of oxygenated air to metallurgical processes has greatly concerned American iron and steel interests, and the industry is making insistent demands for research work of this nature.

The findings of the committee have been incorporated in Serial 2502, "The use of oxygen or oxygenated air in metallurgical and allied processes," which may be obtained from the Department of the Interior, Bureau of Mines, Washington, D. C.

South Lorrain

Report By Cyril W. Knight on Geology and Mining Operations

The geologists of the Ontario Department of Mines are intimately involved in the practical working of the Province's mines. This fact is demonstrated clearly in the Department's latest geological report, "The South Lorrain Silver Area," by Cyril W. Knight (Bulletin No. 48), which was issued three weeks ago on the occasion of the tour of the mining camps by members of the A. I. M. M. E. It is a 55-page excerpt from the larger report on the Cobalt silver area.

The production area of South Lorrain, about 100 acres in extent as at present determined, lies to the north of Trout Lake, three miles west of Lake Temiskaming and 16 miles southeast of the town of Cobalt. Silver was first discovered in 1907 at the Keeley mine, which produced 24,337 ounces up to 1913, and then at the adjoining Wettlaufer mine, the only successful mine of the district up to that time, which yielded 2 1-2 million ounces. At the end of 1922 the total was 4,440,000 ounces.

Pioneers of the New South Lorrain

In 1913 Dr. J. Macintosh Bell took an option on the Keeley property, after an examination that convinced him he would find ore-shoots due to secondary enrichment in the Woods vein, which had been weathered and leached in pre-Glacial times. In spite of the difficulties imposed by the war and his own military service, Dr. Bell hung on, and in 1921 was rewarded by his first important discovery. The price paid for the property was $110,000.

Contemporaneously there was activity on the adjoining Frontier property, where early developments had disclosed a strong vein of smaltite. During 1919 and 1920 there was an active demand for cobalt ore, and in the latter year M. Horace F. Strong bought the Frontier on behalf of American clients and commenced mining smaltite. During the course of this mining he encountered some encouraging silver values, and after the Keeley strike was made in 1921, the property was sold to the Mining Corporation for $525,000. It may be noted, incidentally, that ore won from development during the two years over which payments were due has covered the cost of the property.

Occurrence of Veins

As South Lorrain is still a mining camp in the making, Mr. Knight's report has, quite properly, a forward outlook. He discusses first the occurrence of the known productive veins. These are principally in fault planes, along the top of a sill, with dome-like shape, of Nipissing diabase, and in the overlying rocks of Keewatin age. "In this respect the occurrence is similar to that at the Timiskaming and Beaver Mines at Cobalt. No ore has yet been found in the conglomerate and greywacké of the Cobalt series below the South Lorrain diabase dome. In Cobalt, on the other hand, the rocks below a similar dome, in the Kerr lake-Giroux lake section, have been highly productive, and such mines as the University, Lawson, Crown Reserve, Kerr Lake, and Drummond all occur below the diabase dome in rocks of the Cobalt series."

In the South Lorrain area faults are of prime importance, economically, as the productive veins occur in these. They are very numerous, and the fault system is complex. It is suggested that the numerous sharply defined valleys represent faults. There is some definite evidence for this at Loon Lake and on the Maidens property to the northeast, in the form of fault breccia cemented with calcite and other carbonates. Arguing by analogy, these are good places to prospect.

Discovery of Ore Bodies

"To those, and there are many, who want to know the likely places in which to explore in South Lorrain, the writer can do no better than to point out how success was achieved during the last two years at the Keeley and Frontier properties. The operators began working at the surface on strong calcite veins, an inch to a foot or more in diameter; these veins contained small shoots of smaltite; the silver was negligible. The veins outcropped in Keewatin rocks three to four hundred feet above the top of the Nipissing diabase sill. The operators sank on the veins to the contact of the Nippissing diabase and Keewatin basalt. Exploration of the veins along and near the contact revealed the rich ore-shoots which have brought the camp into such prominence. Another factor, however, besides the diabase contact played its part at the Keeley mine. J. Mackintosh Bell believed that, at or near the bottom of the pre-glacial weathered zone in Wood's vein, he would find rich masses of secondary silver ore which had been leached out of the top part of the vein. While the bottom of the weathered zone has not yet been reached at a depth of 480 feet, there is evidence nevertheless that the workings are approaching it. At any rate, most of the high-grade ore in the mine has been encountered at this depth.

"Those seeking new ore bodies in South Lorrain should also keep in mind the conglomerate and greywacké of the Cobalt series below the South Lorrain dome, in the vicinity of Loon and Oxbow lakes. Up to the present time no calcite veins of importance are known in these rocks under the dome. Should strong calcite veins, with smaltite, be discovered by trenching or diamond drilling such veins might be explored along the base of the Cobalt series. In Cobalt much of the silver ore occurs along the base of that series; similar conditions may exist in South Lorrain under the diabase dome."

This is "straight stuff!" Mr. Knight is to be congratulated on having provided, as a result of his studies, such clear and unequivocal directions for the guidance of practical miners.

Mine Maps Made Available for Public Use

The mine operators have made available to Mr. Knight for his use, the whole of their geological and mine records. Based on the excellent map of South Lorrain made in 1908-09 by Stewart, Bartlett and Burrows, the company maps give the intimate geological and topographical features of the mining properties. It may be noted in passing that the new maps of the Porcupine area now being made by Mr. A. G. Burrows is being compiled similarly from company maps, made available for public use, with the intervening spaces filled in.

The Diabase Sill

Most space is devoted by Mr. Knight, in his discussion of the area's geology, to the dome-like diabase sill whose intrusion caused the forming of the silver-bearing veins. The sheet of diabase, several hundreds of feet in thickness, dips to the north, to the west, and to the southeast and the top of the dome extends to the east shore of Lake Temiskaming, in the province of Quebec. Erosion has cut off the top of the dome, exposing its contact with

the underlying rocks, which are arkose and quartzite, greywacké and conglomerate of the Cobalt series. The evidence available goes to show that the sill was intruded in its present dome-like form, and that subsequent folding has altered its shape very little.

Secondary Enrichment

In regard to the much-discussed question of secondary enrichment, Mr. Knight has this to say:

"It is generally accepted that most of the native silver at Cobalt is primary.

"The primary character of all the silver at the Keeley mine, however, is to be doubted. Some of the silver which occurs in the weathered zone, described in preceding pages, is in all probability secondary, as was first pointed out by J. Mackintosh Bell. It would be difficult, nevertheless, to reach a definite conclusion as to what proportion of the silver in the Keeley mine is primary and what proportion is secondary.

"This much may be said: In the oxidized zone native silver in thin leaves has been found deposited on top of red iron oxides. These red iron oxides are secondary; and hence the leaf silver deposited on top of the oxides is also secondary. Very little native silver, however, occurring under this condition has been noted.

"Again, soft spongy layers of native silver were noted resting loosely on top of smaltite. The sponge silver could be removed with the nail. This silver is doubtless secondary, having been leached out of the upper greatly oxidized zone and precipitated when the silver solutions came in contact with the unaltered smaltite at depth. Little of such silver was noted.

"Probably the ruby silver occurring in geodes and vugs is also secondary. The wire silver, so common at the Keeley mine, is also doubtless secondary.

"Beyond these statements the writer is not prepared to go at the present time. An examination of many polished surfaces of the ore might lead to a more definite idea as to how much silver at the Keeley is primary and how much is secondary.

"More light may, perhaps, be thrown on this subject when mining operations have reached the bottom of the weathered zone....."

"The question has been asked the writer whether the weathered zone will extend south to Trout lake, a distance of about half a mile, and whether it will follow along the bottom of Trout lake a farther distance south of a mile. This can be answered only by exploration of the ground. It is very doubtful, however, if the weathering will persist unless the Wood's or some other fault extends south to Trout lake. The reason that pre-glacial weathering has been preserved is that it followed down Wood's fault along a narrow zone on each side of fault. Glaciation was not intense enough to remove the solid fresh rock on each side of the fault. Hence the preservation of the weathered zone in Wood's fault."

Suggested Importance of Fault Planes and Lamprophyre Dykes

An obvious tip from geologist to miner is contained in the discussion of No. 16 vein on the seventh level of the Keeley. "It is in Nipissing diabase for some distance west of Wood's vein. Where the vein occurs in the diabase it is vertical, but where it enters the Keewatin it dips at an angle of about 60 to the south. This southerly dip is due to the fact that where the vein enters the Keewatin it follows the footfall of a mica-lamprophyre dike and, as the dike dips to the southward at 60 deg., so the vein also has this dip. It is another instance, so common in the Cobalt area, of a vein following the strike and dip of a lamprophyre dike. In every case, of course, the lamprophyre dikes are younger than the Keewatin, but older than the Nipissing diabase. At the time of our examination in October 1922, vein No. 16 had been traced for 100 feet along the footwall of the lamprophyre dike. Vein No. 16 is a fault vein."

Again, in discussing this vein on the sixth level, where it produced 150,000 ounces from a shoot 30 feet by 25 feet, it is noted that "it follows a mica-lamprophyre dike, as on the seventh level." This is true also on the fifth level.

No. 1 vein on the Frontier, in which ten shoots of high-grade ore have been encountered, also displays a tendency to follow a lamprophyre dyke. Another rich vein, the Watson, is in a fault plane, associated with a lamprophyre dyke.

The Maidens underground workings were not available for inspection, being full of water; but Mr. Knight noticed on the dump that "some of the blocks of vein matter show rock fragments cemented with calcite, suggesting a fault plane," and that "blocks of lamprophyre were found on the dump."

This report is characteristic of the tendency among our economic geologists to present to the mining public data and conclusions that are clear and plainly stated, that are not burdened with scientific or pseudo-scientific theory, and that are written in the King's English.

MALAGASH SALT MILL REBUILT

The surface plant at the Malagash salt mine on Northumberland Strait in Nova Scotia, which was destroyed by fire in July, has been rebuilt, and after three and a half weeks' delay, the mine and mill are being operated again under much improved conditions.

The salt mined at present from the Malagash deposit is of unusually high grade, running over 9.9 per cent. sodium chloride and containing only a trace of magnesium chloride. It is the presence of magnesium chloride in salt that makes it hygroscopic, and thereby unsatisfactory for curing dried salt. Malagash salt has now been proved eminently suitable for fish curing, being equal to the best imported salt, which sells at $15.00 to $18.00 a ton, and also being available at the price of the inferior salts.

Malagash salt is also finding a ready market on account of another characteristic. Most of the brands of salt used on the Nova Scotia coasts have been shown to contain bacteria that cause a rusty or reddish colour in the cured fish. The Malagash product does not contain these bacteria, and so is preferred by the fishermen. Thus the Canadian product is rapidly making a substantial market for itself, and at the same time is helping to improve the quality of Nova Scotia salt fish.

GEOLOGICAL GUIDES TO GOLD VEINS

The country rocks near gold ore deposits are usually altered in a noticeable way, which must be studied in each district. Some of the changes are schisting, fracturing, rusty appearance from weathering disseminated pyrite, bleaching of dark rocks, the occurrence of calcite and other carbonates, and the appearance of minerals characteristic of contract metamorphism, such as garnet and epidote. Of these appearances, probably schisting and extensive mineralization with pyrite or the rusty capping resulting from its weathering, are the most useful guides to the prospector.

The Labrador Fizzle

By ALEXANDER GRAY

It is charitable to suppose that J. Lambert Payne, of Ottawa, an official of Labrador Goldfields, Ltd., was taking the sleepy dust out of his own eyes, instead of throwing something into the optics of the public, when he delivered himself of the following after receiving the report of W. Morley Ogilvie, who was sent to the alleged "Eldorado:"

"This is to me a bitter disappointment, I believed in the thing, and to the extent that I influenced some of my personal friends, I feel humiliated and discredited. This simply means, however, that I was deceived along with many others, and I am a loser as well as they.

"I have but one consolation. In all our advertising, we presented the proposition as an absolute gamble. No one could have been misled into the belief they were taking up a sure thing."

According to the daily papers, Mr. Ogilvie "found no gold" and "there is no gold as far as he can ascertain in the district.

Mr. Payne applies flattering unction to himself. Undoubtedly he and his associates (some of them) were deceived by stories that "a couple of men had visited Labrador and claimed to have made discoveries of gold, backing these up by alleged assays." After the display advertising (long after) describing the millions likely to be made out of the Labrador leases, it may be said of Mr. Payne that he awoke. Meanwhile 129 leases had been sold for about $25,800. Probably little of that became available for testing purposes. The advertising and canvassing, office expenses and incidentals of promoters, left little for field work.

When the froth was off, the vessel to convey the expedition to Labrador needed more than froth ballast. About that time, too, the President of Labrador Gold fields, Ltd., was ousted by Mr. Payne and others. Dr. Ledoux of New York also denounced the principals publicly as guilty of a palpable deception. Mr. Payne disclaims all responsibility for this. He admitted that he had been misled; but there was more than this in the matter when Dr. Ledoux told of how two tricksters faked a Ledoux & Company analysis, confessed their culpability and contritely (?) declared they never again would be guilty of doing such a thing!

Responsibility of Public Authorities

Manifestly a good deal of the Labrador propaganda was conceived in iniquity. The Newfoundland Government, by default, allowed promoters to acquire areas and dispose of shares. The Ledoux repudiation of a forged certificate evoked no official admonition. On the contrary, shareholders in one of the Labrador ventures reinstated in office culprits who should have been prosecuted.

One or two Labrador ventures were honestly conducted. They were based upon the representations of men who claimed to have panned gold over an extensive area. It was the Payne organization that displayed the "gamble." Mr. Payne sees the light. Whatever of the public's money has been squandered may serve to emphasize the fact that there was an open season of short duration for a few birds who should be punished. Newfoundland and Quebec authorities might make an example of those who sold leases and misrepresented Ledoux & Company.

As the *Canadian Mining Journal* was the first publication to warm governments and the public against the Labrador "gamble," it may now be permitted to suggest to Mr. Payne in these pages that he add corrective action to his admitted "humiliation and discredit."

Another Chapter Closed

The Montrealers who refrained from misrepresentation and who gave Labrador an honest try-out have decided to abandon the square miles they acquired on Big Brook and elsewhere. They made a sporting bet, and lost. They have nothing further to say, except that the prospectors' dream was a common or garden prevarication, or series of prevarications. All are agreed the placers are mythical and also that the Newfoundland Government cannot escape censure. Where pannings were said to have been obtained one, two and three years ago, there were no colors this year. Black sand was barren of values. It is surmised that the fabled nuggets, about which so much fuss was made, never came from Labrador. One Montreal laboratory was given a sample for assay; but it consisted of fragmentary quartz containing gold. It would have to be crushed and the gold recovered by the usual metallurgical processes.

The flimsiest yarns seem to have enabled crooked adventurers to sell leases as worthless as the words of those who uttered them. Practically all the prospectors have left Labrador. The members of the Montreal party on their return did not hesitate to denounce those responsible for the false representations. Newfoundland alone profited by the adventure; but the profit is dearly won. If Ottawa, Quebec and Newfoundland cannot find a means of punishing those who sold areas and shares, then the public may as well abandon all hope of redress. George Winston, a prospector, on arriving at Sydney, declared that he and a number of his fellows who paid out large sums of money for "gold" claims at Stag Bay and vicinity, would ask the Newfoundland Government to proceed against the heads of various corporations that sold claims. Furthermore, Winston asserts "there isn't enough gold in Stag Bay to cover a penny."

COPPER RESERVES IN KATANGA

At the annual meeting of the Union Minière in Brussels recently, it was disclosed that the company's mines in the Katanga, Belgian Congo, have 68,000,000 tons of ore in reserve, containing 4,500,000 tons of copper. The smelters made 43,362 tons of copper in 1922, against 30,464 tons in 1921. For the first six months of 1923 there was produced 24,500 tons of copper. A leaching plant is to be installed. In addition to copper, the company is treating successfully ores of tin, cobalt and radium.

LOW GOLD MINING COSTS

At the Shamoa mine in Southern Rhodesia gold ore containing 3½ dwt. per ton is treated for 9s. per ton. The ore is mined by means of adits. The plant consists of crushers, 64 Nissen stamps, twelve tube mills and sand and slime plants, cyanide solution being used throughout. The capacity is 30,000 tons a month.

The Hidden Creek Mine

Dr. Victor Dolmage Describes the Mine that keeps the Anyox Smelter Busy

Last summer Victor Dolmage, of the Geological Survey, Ottawa, mapped 200 miles of the coast of British Columbia, from Stewart southward, thus completing a survey of the coast commenced in 1905 by the late O. E. Leroy. An interim report is published in "Summary Report, 1922, Part A." The area includes the important mineral areas at Stewart, Alice Arm, Surf Inlet and Anyox. The following is, in part, Dr. Dolmage's description of the Hidden Creek Mine at Anyox:

Largest Copper Deposit in B. C.

The largest deposit of copper is that of the Hidden Creek mine at Anyox, owned and operated by the Granby Consolidated Mining, Smelting, and Power Company. This is the largest copper deposit in British Columbia and is at present producing nearly 3,000,000 pounds of copper per month. A very excellent and complete report on the deposit had, shortly before the writer's visit, been finished by J. Austen Bancroft, formerly assistant general manager of the company. This report, and the geological maps accompanying it, were kindly placed at the writer's disposal. With the help of these, and the observations made during several days on the premises under the guidance of F. E. Patton, the company's mining engineer, a good knowledge of the deposit was obtained. The following report is largely a restatement of facts from Bancroft's report, with a few observations by the writer.

The mine is situated about 1 mile north of Granby (formerly Goose) bay, on the west side of Observatory inlet justs at the junction of Hastings and Alice arms. A smelter with a daily capacity of 3,000 tons is situated on the shore of Granby bay. The ore, which is very high in sulphur, is smelted directly in blast furnaces by a process of partial pyritic smelting without previous roasting or concentrating. The matte from the blast furnaces is blown to blister copper in converters and the blister copper is shipped to the Nichols Chemical Company, New York, where it is refined.

Occurrence of the Ore

The ore-bodies are well to the centre of a large body of greenstones and metamorphosed argillaceous sediments which forms an inclusion in the Coast Range batholith. The contacts of the inclusion with the batholith lie about 4 miles to the north and 5 miles to the south of the principal ore-bodies. The contact between the greenstones and argillaceous sediments lies about 1½ miles northwest of Granby bay. The greenstones lie to the west and extend to Portland canal and beyond. The ore-bodies lie on or adjacent to the contact between the greenstone and argillites. This contact has a northeasterly trend, but is exceedingly irregular owing partly to faulting. The dip of the contact is almost vertical in the upper levels, but flattens considerably in the lowest workings. Owing to its irregularity, also to the highly folded and mashed condition of the argillites in its vicinity, and to the intense hydrothermal alteration, the true nature of this contact is difficult to determine...

The Coast Range batholith, which surrounds the inclusion and which occupies most of the territory in the vicinity of Portland canal and Observatory inlet, is composed of granodiorite in which quartz forms about 40 per cent, biotite and hornblende about 10 per cent, and feldspar 50 per cent of the rock. The feldspar consists of one-third orthoclase and microcline and two-thirds oligoclase and oligloclase-andesine.

At 3,200 feet northwest of the mine there is a band of coarse diorite about 250 feet wide, striking north 20 degrees to 50 degrees east, and lying nearly parallel to the greenstone-argillite contact.

The only other rocks in the vicinity are numerous dykes. As these were virtually all injected after the deposition of the ore they have no significance as to its origin; but their abundant presence in the ore-bodies has a distinct tendency to lower the grade of the ore, since most of them have to be mined.

The Ore-Bodies

There are seven ore-bodies. Numbers 1 to 5 are clustered close together about the apex of a spur of greenstone about 2,500 feet square which juts out into the argillites in a northeast direction. The sixth ore-body lies 1,300 feet to the southwest on the southeast side of the above-mentioned spur of greenstone. Another ore-body, which is really a separate deposit, but is owned by the same company and known as the Bonanza, is situated 3½ miles to the south on Bonanza creek and 3,200 feet from the shore of Granby bay. This deposit is also on a contact between the argillites and a small mass of greenstone less than a mile in diameter.

Ore-bodies 1, 4, 5, and 6 lie on the contact of the argillites and greenstones, where the argillites are much crumpled and the greenstones are especially schistose. Numbers 1 and 5 have developed where the turn in the strike of the greenstone-argillite contact is most abrupt. These ore-bodies are richer where the slate contact overhangs the ore. Ore-bodies 2 and 3 and Bonanza lie in the greenstone, where it is especially schistose, and 2 and 3 are so situated that at the time of their deposition they were probably roofed by slate.

Ore Reserves

The following dimensions will give some idea of the sizes of the ore-bodies. Ore-bodies 1 and 5 have a combined length on the 530-foot level of about 1,240 feet, with an average width of 150 feet. Number 3 is a faulted block of Number 2 and they have a combined length of 750 feet with a width of 240 feet. Number 4 ore-body lies chiefly above the 530-foot level. It is triangular in plan with a length on the 760-foot level of 560 feet. The present workings extend over a vertical range of 800 feet and diamond drilling has proved the ore-bodies to extend still deeper. They have a maximum size in cross-section on the 530-foot level, below which there is a gradual decrease in size which becomes more marked below the 150-foot level and is coincident with a sudden flattening of the greenstone-argillite contact.

There has been developed up to date on ore-bodies 1, 2, 3, 4, 5, 6, and 7, 13,215,000 tons of high-grade ore, averaging 2.14 per cent copper, and 1,534,000 tons of

low-grade ore, carrying 0.94 per cent copper. The Bonanza deposit contains 488,800 tons of 2.49 per cent ore and 577,300 tons of 0.64 per cent ore.

Composition of the Ore

The chemical composition of the ore is very well shown in the following tables which are averages of a great many determinations.

High grade Ore

Ore-body	Gold in oz. per ton	Copper %	Insoluble %	Silica %	Iron %	Sulphur %	Alumina %	Magnesia %	Lime %	Silver in oz. per ton
No. 1	0.013	2.08	26.1	22.7	29.8	30.1	4.6	1.2	5.0	0.40
No. 2	0.006	2.11	37.6	31.4	26.0	18.2	10.3	3.8	3.2	0.25

No. 5	0.003	0.66	45.8	41.5	24.8	19.0	5.1	n.d.	3.3	0.25
No. 6	0.003	0.74	62.3	55.8	14.6	9.6	10.1	n.d.	3.6	0.19

The total ore shipped from 1918 to 1921 inclusive from ore-bodies 1, 2, 3, 5 yielded 0.008 oz. of gold and 0.49 oz. of silver to the ton.

The mineralogical composition of the gangue and ore is comparatively simple and very constant. The gangue consists of silicified argillite and greenstone averaging 50 per cent silica. Scattered among the sulphides as loose individual grains are found biotite, hornblende, actinolite, epidote, quartz, and calcite; being by far the most abundant. The hornblende of this ore is of a much darker colour than that of the greenstone. The calcite is present in small disseminated grains, and seldom occurs as late veinlets cutting the ore, in the manner so common to most of the copper deposits of the Pacific region.

Minerals of the Ore

The common metallic minerals are pyrite, pyrrhotite, chalcopyrite, zinc blende, magnetite, and arsenopyrite. These constitute nearly 100 per cent of the ore, but Bancroft found also small amounts of galena, and the writer found in some high-grade ore from the Number 1 ore-body, on the 530-foot level, a small amount of native silver, associated with some arsenopyrite, and a very small amount of a soft grey mineral which is almost certainly argentite. Number 4 ore-body is different from the others. It is composed almost entirely of pyrite, in the form of small crystals less than one-sixteenth of an inch in size, cemented with calcite. Surrounding this central mass is a shell of nearly pure pyrrhotite. The copper content is so low that this ore is sold as pyrite ore.

In general the pyrite, arsenopyrite, and magnetite were deposited earlier than the pyrrohotite, zinc blende, and chalcopyrite, but in two specimens veinlets of pyrite were found cutting the pyrrhotite and chalcopyrite. The three sulphides — chalcopyrite, zinc blende, and pyrrhotite — were deposited simultaneously. The small amount of argentite occurs as rounded blebs of microscopic size in the chalcopyrite. Its age was not indicated, but it was probably precipitated at the same time as the chalcopyrite. The native silver occurs in a similar manner and is probably of the same age.

Origin of the Ore-Bodies

Regarding the origin of these ores it is Bancroft's opinion that they were formed by the replacement of greenstones and argillites by solutions that began to circulate towards the close of the intrusion of greenstones, and continued during the advance and cooling down of the Coast Range batholith. He considers the possibility of there being two periods of silicification, one related to the greenstone intrusion, and a later and more extensive one related to the invasion of the batholith; but says that the field evidence is in favour of one prolonged period of silicification and mineralization. This would involve a tremendously long period of time for the formation of these deposits. There is no doubt, however, that the great bulk of the metal of these deposits, as of all the deposits of the coast region, originated in the Coast Range batholith.

The immediate future for the Hidden Creek mine looks very bright. The costs are fairly low and the price of copper is much improved. The cost in May, 1922, of one ton of ore delivered at the smelter was $0.949.

The ore reserves on July 1, 1922, were:

Ore-body	High-grade		Low grade	
	Tons	Copper per cent	Tons	Copper per cent
1	3,866,000	1.94	672,000	0.87
2	2,305,000	1.87	269,000	0.96
3	1,188,000	1.82	427,000	1.00
4	139,000	1.90	55,000	1.20
5	1,047,000	2.90	111,000	0.90
6	255,000	2.44	. . . .	. . . .
Total	8,800,000	1.97	1,534,000	0.94
Bonanza . . .	488,800	2.49	. . . .	. . . .

This reserve will last at the present rate of production for about thirteen years.

The city of Boston has bought 15,000 tons of Welsh coal at a price less than the $15.50 charged for Pennsylvania there.

DESULPHURISING POWER OF BLAST-FURNACE SLAGS *

By RICHARD S. McCAFFERY and JOSEPH F. OESTERLE (Madison, Wis.)

This investigation was undertaken to determine the quality of different blast-furnace slags as desulphurising agents, and the possibility of using in the blast furnace, materials of higher sulphur content than is now usual. The solution of this problem would render possible the use of higher-sulphur iron ores for pig-iron, the use of cokes containing more sulphur than now employed, and the economic manufacture of iron and steels of lower sulphur content.

It is generally assumed that the sulphur that reaches the lower part of the blast furnace is removed from the iron by combining with lime to form calcium sulphide. Most of the sulphur introduced with the charge is in combination with iron or manganese, or perhaps in the coke, as a carbon compound. Iron and manganese sulphides are more soluble in iron than is calcium sulphide, but as the latter is more soluble in the slag, this fact tends to free the metal from sulphur. The reaction $FeS+CaO+CO=Fe+CaS+CO_2$ requires a high temperature and strongly reducing conditions in the presence of lime.

The investigation of sulphur solubility was begun by determining the solubility of calcium sulphide in each of the three minerals, anorthite, calcium bisilicate, and gehlenite, which constitute the largest part of the ordinary blast-furnace slags. Mixtures of chemically pure lime, alumina, and silica were made in the proportions present in anorthite, and calcium sulphide was added to these in definitely varying amounts. The slags resulting from these melts were carefully analysed, and the results reported are on the basis of these analyses. A series of cooling curves was determined for anorthite with these different percentages of calcium sulphide. This work amounts to the determination of the equilibrium of the binary systems: $CaS—CaO.Al_2O_3.2SiO_2$, $CaS—2CaO.Al_2O_3.SiO_2$, and $CaS—CaO.SiO_2$.

The system calcium sulphide-anorthite forms a eutectic with 6 per cent. calcium sulphide, melting at 1,440 deg. C., with a probable compound containing 11 per cent. calcium sulphide melting at 1,500 deg. C. In a similar way, the equilibrium of the system $CaS—CaO.SiO_2$ (calcium bisilicate) showed a eutectic of 2 per cent. calcium sulphide melting at 1,200 deg. C. For the system $CaS—2CaO.Al_2O_3SiO_2$ (gehlenite) the eutectic contains 4.5 per cent. calcium sulphide, and melts at 1,390 deg. C., and a probable compound containing 6 per cent. calcium sulphide, melts at 1,460 deg. C.

With the equilibrium of the systems being known and plotted, the solubilities of calcium sulphide are then indicated by the intersection of the horizontal temperature lines with the liquidus curve.

From these calcium sulphide solubilities, and the mineralogical composition of slag of any analysis having been determined, the solubility of calcium sulphide in slags within the range of composition generally employed for iron-furnace slags, and extending well beyond this, were calculated at temperatures of 1,350 deg., 1,400 deg., 1,450 deg., 1,500 deg., 1,550 deg., and 1,600 deg. C. In the same way, the solubility of manganese sulphide was ascertained, first in the individual slag components and then in slags of stated composition and at these temperatures.

Solubility of Calcium Sulphide at Various Temperatures, in Percentage of Total Melt

Degrees C.	Bisilicate	Anorthite	Gehlenite
1600	40	42	44
1550	31	33	35
1500	22	24	27
1450	13	16	18
1400	4	17	10
1350	4	17	10

Summary of Results

(1) The effect of alumina in blast-furnace slags is to increase the solubilities of the slags for calcium sulphide and to diminish their solubilities for manganese sulphide.

(2) The effect of high temperatures in increasing the solubilities of the slags for both calcium and manganese sulphides is very marked.

(3) The actual chemical composition of the slag, as affecting the solubilities of calcium and manganese sulphides, is of less importance than the temperature of the slag.

(4) The change in calcium and manganese-sulphide solubilities is probably less influenced by the basicity of the slag chemically than it is by the indirect action of the more basic slag in increasing the hearth temperature.

(5) The region in which solution of calcium and manganese sulphides in the slag is most rapid is the hearth of the blast furnace.

* From a Paper read before the Montreal meeting of the American Institute of Mining and Metallurgical Engineers.

WASTE OF MANGANESE ORE

Wasteful methods in the washing of manganese ores, produced in the Kutais district in the Caucasus, are depriving the world of enormous supplies of this material, according to a statement made by C. E. Julihn, representing the United States Department of the Interior. Such waste is of international interest, Mr. Julihn emphasizes, because of the relatively small reserves of high-grade manganese known to exist and the importance of such ores in the manufacture of steel.

A study of the preparation of the Kutais ores, made by J. W. Furness, associate mining engineer of the Bureau of Mines, develops the fact that the tremendous wastes now occurring are due to the desire to meet an unreasonable and unnecessary trade requirement calling for manganese of 52 per cent grade. An annual production of approximately a million tons of ore containing 52 per cent manganese is made from the Kutais deposits by washing ore which averages 47 per cent of the original manganese. This means in effect that, in order to make an improvement of 5 per cent in grade, about one-half the manganese mined is lost in washing.

The Bureau of Mines investigation developed that about 20 per cent of the production from these deposits is marketed in the United States, 40 per cent in Great Britain, and the remainder in France, Germany, and Italy. To these countries, which are the great steel producers, the conservation of high-grade manganese is especially important.

It was pointed out by Mr. Julihn that there are no established international agencies authorized to consider

such unwarranted wastes of the world's precious natural resources. The consumers, he declared, are most concerned with obtaining the highest possible grade of material without thought or responsibility as to the future of world industry. It is hoped that the calling of attention to these serious manganese losses may lead to some means of remedying the situation and thereby establish a precedent for the correction of other unsound international trade practices.

ANOTHER SECTION OF THE YUKON MAPPED

"In reviewing the published descriptions of the mineral deposits of Whitehorse, Wheaton, and Conrad districts, it was found that whatever the genesis of those deposits has been established it is attributed to the intrusion of the Coast Range batholith. It was, consequently, considered advisable to map the eastern edge of these granitic rocks in order that prospectors might know more precisely the location of the zone, adjacent to these rocks, in which ore-bodies are likely to occur. With this in view, the writer commenced mapping such parts of the area lying between longitudes 134 and 136 degrees and latitudes 60 and 61 degrees as had not already been mapped."

These were the marching orders of W. E. Cockfield in the spring of 1922, and his interim report was published in *Summary Report,* 1922, *Part A.* The area lies to the west of the railway between Skagway and Whitehorse and is underlain by rocks ranging in age from pre-Cambrian schists to lava flows of Pleistocene or Recent times.

The principal geological feature is the Coast Range batholith, which is almost exclusively the rock of the western part of the area. In the central part the present land surface corresponds closely with the original roof of the batholith, so that many inclusions or "islands" of the intruded rocks remain. The eastern portion of the area is believed to be underlain also by the batholith. Obviously it is good prospecting ground.

The prospecting already done, most of it carried on ten to twenty years ago, has disclosed deposits of copper, gold-silver, silver-lead and antimony-silver ores, as well as coal. None of the deposits are being worked at present. Dr. Dolmage examined a few of these deposits, and suggests that, in view of the small amount of development done, further work might disclose ore-shoots that would pay in spite of the distances from the railway. In every case the origin of the ore-deposits can be attributed directly to the intrusion of rocks connected with the Coast Range batholith. As there is no demand for coal in southern Yukon, no prospecting for it is being carried on at present.

REVISED SILVER STATISTICS FOR 1922

The Dominion Bureau of Statistics has issued the following finally revised statistics on the production of Silver in Canada during 1922, under date of August 17th.

Special Note.— Prior to 1922, the method used in compiling the statistics on the silver production of Canada was to include, except for Ontario, the quantities of silver produced from Canadian ores either in Canadian or foreign smelters. For Ontario, the sales of silver bullion from the mines and smelters were considered as the year's production. In order to bring the practice for Ontario into harmony with that used in computing the silver output for the other provinces, adjustments amounting to 1,222,450 ounces have been made for 1922 to take account of the stocks of silver bullion on hand at the end of 1921 which had not been previously included in the reports of the mineral production of Canada.

As above defined, the production of silver in Canada during 1922 amounted to 18,581,439 fine ounces which at the average price for the year of 67.251 cents an ounce was valued at $12,576,758 as against 13,543,198 fine ounces valued at $8,485,355 for 1921, an increase of 37 per cent in quantity and 48 per cent in value.

The production in 1922 included (a) silver contained in silver and gold bullion (including the adjustments noted above) 10,032,909 fine ounces or 54.0 per cent, (b) silver contained in blister copper and lead bullion, 3,502,367 fine ounces or 18.8 per cent, (c) silver estimated to have been recovered from ores, etc. exported, 5,046,163 fine ounces or 27.2 per cent. The corresponding figures for 1921 were (a) 9,080,718 ounces 67.0 per cent, (b) 1,649,057 ounces or 12.0 per cent, (c) 2,813,423 ounces or 21.0 per cent.

The monthly average of the New York quotation for silver which was 65.540 cents per ounce in January rose to 71.154 cents in May and than gradually declined until in December the average quotation was 63.805 cents.

Total for CANADA	18,581,439	12,576,758

INFUSORIAL EARTH

Infusorial and diatomaceous earths—sometimes called tripolite—are very light and extremely porous materials composed of pure silica which have been laid down under water and consist of the remains of microscopical infusoria and diatoms.

The former are animal remains, and the latter are from plants. The principal commercial use of this material is as an absorbent. It is also employed in the manufacture of scouring soap and polishing powders; for filtration purposes; in making some classes of refractory brick; and as an insulating medium both in heating and refrigeration. It is a first class non-conductor of heat, where high temperatures are employed, such as around steel and gas plants and power houses. In such cases, it is built in as an insulating layer in furnace walls. In Germany, under the name 'kiesel guhr,' it was used as an absorbent for nitro-glycerine in the early manufacture of dynamite.

As a non-conductor of heat it has been used alone or with other materials as a covering for boilers, steam pipes, and safes and in fireproof cements. It is used largely by paint manufacturers as a wood filler. Boiled with shellac it is made into records for talking machines. It has been used for absorbing liquid manures so that they could be utilized as fertilizers, and as a source of silica in making water-glass as well as in the manufacture of cement, tile glazing, artificial stone, ultra-marine and other pigments of aniline and alizarine colors, paper filling , sealing wax, fireworks, hard-rubber objects, matches, and papier-maché, and for solidifying bromine. For making insulating brick the material is sawed into blocks, and for all other purposes it is ground and screened.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NOVA SCOTIA

Canon Scott's Blue Glasses. — The saying is just as true today as when it was first uttered, "Seek and ye shall find"; men usually find what they seek. Canon Scott says he came to Cape Breton seeking certain things, — and he found them. He would have been just as successful in finding if he had sought to see the better side of conditions at the Cape Breton collieries. After dealing with the appearances and the sanitary conditions of the company houses and bath houses at the collieries, the wages paid to some few mine workers, he sums up by stating publicly that "the general atmosphere is one of gloom and a spirit of depression pervades the whole region; the men do not trust the company and the company do not trust the men."

Had the venerable Canon visited No. 4 colliery say sixty years ago, he would have found the houses all newly built in the style of the day, and looking spick and span. Change and decay attack both men and houses, and if these latter do look the worse for wear (as does the good Canon himself), it is only natural. He selected the oldest colliery in the district for his first visit, and surely he did not expect to find signs of youth and beauty. Seemingly nothing about the colliery pleased him. We would not like to say that the Dominion Coal Company is altogether pleased with all the conditions at this or any other mine; but they cannot change all the old things and make them new to please Canon Scott or anyone else. The best that can be done is to keep the houses in good repair and comfortable, and the miners themselves see to it that this is done. They need no one to speak for them in this matter, for they do get close enough to the company to co-operate, and there is a thorough understanding that company houses are to be kept in repair. The rent paid is not high, ranging from two to eight dollars per month according to the size. For a four to eight-room house, no one will say that this rent is excessive. In addition to the house there are fairly large plots of ground that can be used for gardening or for playgrounds as the miner and his family see fit.

The Bath House Problem. — The bath house at Caledonia is an old one, but although the Canon has not said so, no doubt he was told that a new one had been designed and will be erected just as soon as the Company can get round it. He was shown a model bath house at No. 2 colliery, and could have had the pleasure of seeing others if he had cared to visit them. These bath houses are not surpassed on the continent for convenience and comfort, and it is the intention of the Coal Company to have every bath house remodelled where the prospective life of the colliery warrants it. Rome was not built in a day; and the British Empire Steel Corporation since it took hold has had many things of this nature to do. They have spent enormous sums om money in making these changes and are not by any means through with that work.

Miners Prefer Motor-cars to Good Houses. — The building of houses is one of the most serious questions facing the coal companies today. It seems probable that this will be one question that in the future will curtail very largely the output of this and other coal companies of the Province. To build a house and equip it with all modern conveniences would raise the cost of coal to an exorbitant price. Miners would not pay the rents asked, neither would buyers of coal willingly pay the price. Indeed, as the market is today, Nova Scotia could not compete and conditions at the collieries would be worse instead of better. The average miner of Cape Breton has caught the spirit of the age, and for a change of scenery he will go out into the country, as do many others. Many of them who live in company houses rented at a low rate possess very fine automobiles, and prefer these to paying high rents or even to becoming owners of their own houses.

Too Much Meddling by Outsiders. — But why should miners be singled out as a class apart from all others, for public sympathy and public pity? The majority of miners do not thank these self-appointed benefactors; they resent all this humbug about the low conditions and low standard of living at the collieries and are tired of the whole business. In "military" language, they are "fed up" and want no more of it.

The time has come when the industries of Nova Scotia should cry "hands off." The Province has all too few industries, and these few are being ridden to death by men who add nothing in the way of information or inspiration. There is nothing to hide at the collieries, but there is much more to learn than can be accomplished by a Canon on a flying visit. Providence has supplied an abundance of coal; but in many respects the coal fields are at a disadvantage compared with those of the United States. The natural conditions are hard to overcome, which increases the cost. The climate is severe, and except in summer, transportation at a profit is impossible. Yet we have wiseacres with vision of a new heaven and a new earth, who believe all can be changed tnd Utopia ushered in with a wave of the magician's wand. It cannot be done, and we must take things as we find them and make the most of them.

Miners Get High Wages. — With regard to wages, the Dominion Coal Company would profit by making a public statement of wages earned at their collieries. They are in a position to show to the public that, except for a few men who are getting the minimum wage, the miners do earn unusually large wages. Indeed, many miners earn twice as much as the salaries paid to some of the professional men in the colliery districts.

Nova Scotia has within the last two years been cursed by commissions and agitators. The minds of the workers have been for a time buoyed up by false hopes, only to be cast down after fruitless investigation has revealed nothing new and has made no changes. "Laissez faire" should be the slogan for Nova Scotia industries just now.

The Ford Motor Company has under construction an electric furnace of 60 to 80 tons capacity, built on the lines of an open-hearth.

ROYAL CANADIAN AIR FORCE

The Department of National Defence, Ottawa, has made an announcement through the columns of *Natural Resources* of the provisions for the co-operation of the Royal Canadian Air Force with various other government departments.

The increasing demand on the Royal Canadian Air Force for aerial transportation in connection with forestry, survey, inspection, and related work and for transportation for those services working in the remoter parts of the country, made it desirable to form some organization where the problems incidental to this work could be considered, and as a result an inter-departmental committee on flying operations for the civil services of the Government of Canada has been constituted. The committee will provide for the interchange of information between the various services interested, for the consideration of the results obtained, the co-ordination of flying programmes throughout the country and discussion of all matters arising.

The first meeting of the committee was attended by representatives of the following services:—

Department of the Interior: Surveys Bureau, Topographical Survey, Forestry Branch, National Parks Branch, International Boundary Commission, North West Territories Branch, Geodetic Survey, Dominion Water Power Branch, Dominion Observatory.

Department of Mines: Geological Survey.

Department of Agriculture: Entomological Branch, Experimental Farms Branch.

Department of Public Works: Chief Engineer's Branch.

Department of Indian Affairs.

The programme of flying operations for 1923 was discussed and information was given to the meeting as to the nature and extent of the operations contemplated. By giving all services full information as to the whole programme it has been possible to consolidate the work and arrange for co-operation between the various departments served so that operations undertaken in any district may serve as many departments as possible.

IRON FORMATION

"Iron formation," an expression used a good deal in pre-Cambrian geology, consists of iron ore such as siderite, magnetite, or hematite, with more or less silica in the form of chert, jasper, etc., generally in bands, but sometimes not distinctly so. The bands of iron ore are at times high-grade, but are often mixed with a good deal of silica, the whole making an ore too lean for use without concentration. Iron formation is believed to be of sedimentary origin.

Limonite is sometimes formed in large quantities by the weathering of the sulphides of iron; such gossan has occasionally been used as a iron ore. At Bannockburn, Ontario, a pyrite deposit was discovered below limonite which was being mined as an iron ore; this gossan capping of the pyrite was from eight to fifteen feet deep.

Manganese, like iron, is present in all rocks, but not so plentifully as iron. In the weathering of rocks, manganese is more easily dissolved than iron; but, on the other hand, iron is more easily precipitated from the solution. These differences account for the separation of iron ores from manganese ores in sedimentary deposits.

AIR Engineering Service

The Canadian Sirocco Company, Ltd. offers the cooperation of a competent Engineering department in the solution of any problem along the following lines:

PRIMARY VENTILATION
SECONDARY VENTILATION
FANS AND BLOWERS
MECHANICAL DRAFT

Canadian Sirocco service and mechanical equipment represents the development of forty successful years. Write for descriptive Bulletins.

"Telsmith" Primary Breakers

Shatter Rock Breaking Costs

A fundamental advantage of the Telsmith Primary Breaker is the parallel crushing stroke. Telsmith exerts the full stroke on the big lumps just as they enter the bowl. The initial bite is a long, horizontal, bull-dog grip that doesn't let go. It just fairly eats into the rock, increasing the capacity, reducing the labor in the quarry and over the crusher. But there are other things which have assisted the Telsmith Breaker to its predominant standing in the coarse crusher field. For instance:

While the width of the opening is the same, as in other gyratory crushers, in every other dimension of the concave bowl, crushing cone and feed openings, Telsmith is 25-35 per cent bigger than other crushers. Don't take our word for it, but measure up the machines, and compare the horse power requirements. When you have done that, you'll not be surprised to find that there are well over 500 Telsmith crushers in use today.

The
British Empire Steel Corporation, Limited

by reason of the magnitude of the operations of its constituent companies, is able to render a wholly unique service to the industrial organizations of the world—and of Canada in particular.

The vast scope of these operations necessitates the maintenance of the highest possible standards of efficiency and economy, which, naturally, reacts to the benefit of our customers.

Roll Call!

A roll call of the Great Industries for Canada could be made from the books of this company.

Certainly no user of Power Transmission Machinery would be absent from it, and in many instances the transactions would show a permanent increase of business from generation to generation- A few outstanding customers are :

Alberta Pacific Grain Co.
Bell Telephone Co. of Canada.
Brompton Pulp & Paper Co.
Canadian Locomotive Company.
Canadian National Railways.
Canadian Pacific Railway.
Dome Mines Company.
Dominion Bridge Company.
Dominion Iron & Steel Corpn.
Donnacona Paper Co.
E. B. Eddy Company.
Fraser Companies.
Lake of the Woods Milling Co.
Laurentide Power Company.
Maple Leaf Milling Company.
Massey-Harris Company.
Ogilvie Flour Mills Company.
Price Brothers & Company.
Quaker Oats Company.
Steel Company of Canada.
Spanish River Pulp & Paper Co.
Wayagamack Pulp & Paper Co.

We would stress the point that, while we do big work in an efficient way, we are equally keen to secure small orders for Shafting, Hangers, Pulleys, Couplings, Friction Clutches and Belting.

Buyers will find that we are just as reliable and as faithful in our care for modest business as we are in our conduct of large transactions.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387
	Dividends.		

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario

Publications

For list of publications, illustrated reports, geological maps and mining laws, apply to

Thos. W. Gibson,
Deputy Minister of Mines.
TORONTO, CANADA

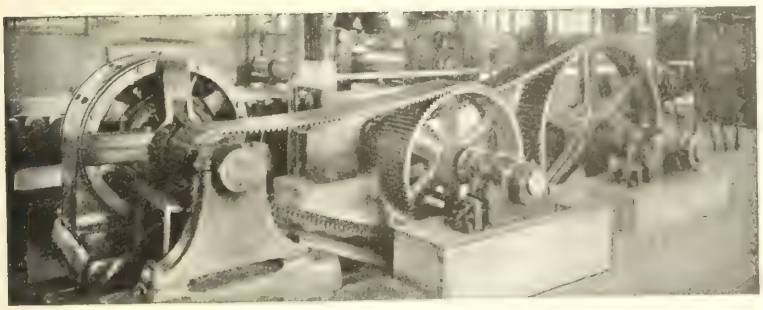
MORSE CHAINS

THE MORSE "ROCKER JOINT"



A few of the Morse chains in use at the Raymond Lead plant

Using chain drives speeds up production, cuts belt expense and overtime wages and operates with practically no repairs.

O. W. Ludwig, *Plant Superintendent of the Raymond Lead Co., Chicago, says:*

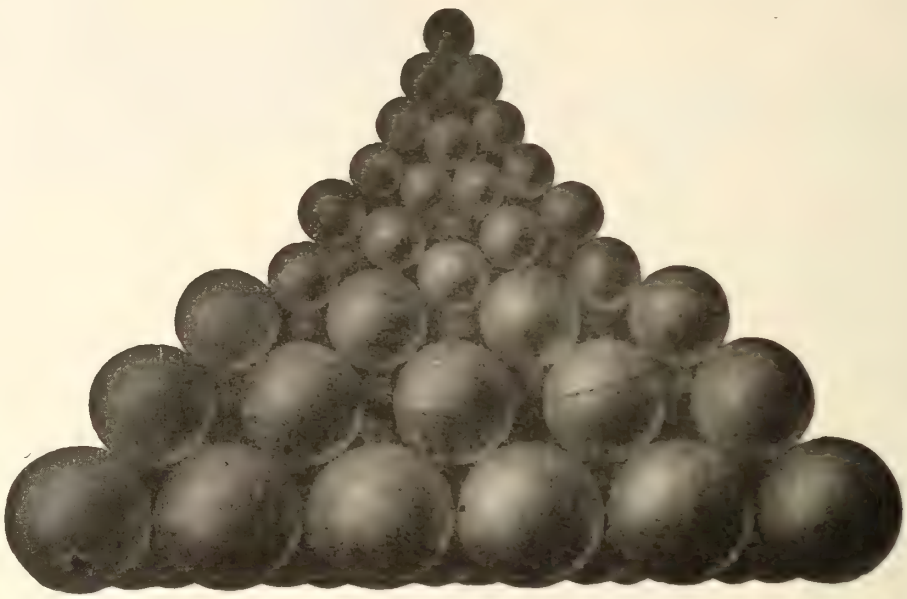
"Thirteen years of service without a repair is our experience with two 100 H.P. and ten 20 H.P. Morse Silent Chain Drives.

"When we moved into our present plant thirteen years ago, we installed the present Morse equipment of silent chains for our two lead mills and ten hydraulic pumps. We had always previously used leather belts, but not without considerable trouble. For instance, if the operator was not careful—and gave the motors too great a load, the leather belt would slip and in some cases burn out. While with the Morse Chain Drive we overload them at times up to 15 H.P. without the slightest trouble.

"When we used leather belts on the hydraulic pumps, if a pump packing suddenly gave way, the water would squirt all over the pump as well as adjoining pumps, causing the leather belts to get wet. This often necessitated a shut-down on 3 to 4 pumps to dry out each belt, thus causing a loss of time by the men, which resulted many times in paying overtime to catch up on the work. Of course, with our Morse Chain Drive we have no such trouble—this positive drive prevents slippage and is not affected by water.

"Leather belts lasted us 2 to 3 years at the most, while our Morse Chain Drives have already lasted 3 to 4 times that long and seem good for many more years. So Morse Drives have cut our expense materially, speeded up production, cut out overtime wages and saved floor space, for they operate on shorter centers."

Decrease your grinding costs.



USE HISCO BALLS

"If quality counts use 'Hisco' Products" *Hisco Balls* are noted for superior quality. They are in use in the largest ore and cement mills from Halifax to Vancouver. Forged from Electric Furnace chrome steel, absolutely the best ball on the market.

Sizes 3, 4, 5 and 6 inch carried in stock.
Special sizes from 6 inch up made to order.

Adding Impetus To The Development of Mining

The development of Canada's enormous natural resources will affect her whole future. Her vast mineral wealth, as yet practically untouched, is to-day attracting world-wide interest from far-seeing investors.

It is appropriate that the Imperial Bank, whose policy has ever been to concentrate exclusively on Canadian affairs, should be powerfully furthering that interest. This Bank, by placing branches at strategic points throughout the mining districts, has materially aided the whole industry.

Those who contemplate becoming connected in any capacity with mining would be well advised to take advantage of this Bank's facilities.

GOLD MINING QUEBEC'S BEST COLONIZER

Last month a farm of 160 acres near Timmins, Ontario, was sold for $20,000. Twelve years ago it was a homestead, with only its proximity to the then little mines, Hollinger and McIntyre, to recommend it. Today the products of its fields and pastures are sold, a couple of miles away, in one of the best markets in Canada.

In the Chelmsford valley, running northwest from Sudbury, is some of the most valuable land for mixed farming in Ontario. Had not the nickel mines and smelters been developed hard by, the farmers would barely find it worth while to till their fields. As it is, the valley is prosperous and the farming land, like its products, sells at high prices.

The valley of the Blanche River, around and north of the head of Lake Temiskaming (the "little clay belt") is now one of Ontario's prosperous farming districts. Without the adjacent mining communities to provide lucrative markets and to stimulate rapid settlement, the farmers of this district would have had a struggling existence for two generations.

There is an active desire on the part of the provincial authorities of Quebec to keep their people within the province, by settling the large areas of good farming land that still are in the grip of the forest. A large proportion of the province's income is being used to this end, and an active and consistent propaganda is being conducted. The effort is resulting well; but the same effect could be had at a fraction of the expense and labour if the aid of the mining industry were secured.

Thousands of Quebec's best colonists are coming across to Ontario annually to settle in the vicinity of the new mining camps. This is of mutual benefit to the settlers and the miners; the settler has at once the best market in the country for his products, and the miner's table and pocket book both show a corresponding benefit. Ontario is benefiting doubly from the discovery and development of her mineral resources; there is the direct profit from the mines, represented tangibly in mining taxes, and there is also the settlement of the land that invariably accompanies the mining operations. In addition, more remote parts of the province are benefited through the increase in trade in commodities of all sorts; manufacturers, merchants, professional men — all derive a profit from the new development.

The provincial administration at Quebec obviously do not understand the importance of mineral development in the general development of the province. They have been generous, even lavish, in their provision for colonization. They are starving their Bureau of Mines, which is responsible for mineral development. In 1909, when the Bureau was reorganized on its present basis, its income was $14,000. Today its income is $16,500. During these fourteen years the Province's mining industry has increased fourfold in annual production; ten per cent. has been added to the Bureau's income.

The Bureau of Mines is manned by a Superintendent, his assistant, and three clerks, one of whom is now on detached duty as mining recorder and hence unavailable for service at headquarters. The Deputy Minister of Mines is likewise the deputy for Colonization, Forests and Fisheries, with the result that the Bureau of Mines gets little or none of his time.

The Superintendent and Assistant Superintendent of Mines assess mining taxes and collect them; they inspect the mines and investigate all fatal accidents; they collect and compile the mineral statistics and prepare the annual report of the Bureau; they attend to the Bureau's extensive correspondence; they formulate policies and advise the Government on appropriate action; they conduct the province's geological surveys. How can two men do all this? They can't.

The Bureau of Mines at Quebec, and the province's mining industry, are suffering from malnutrition; they are being starved. Neither will grow in the natural way until more funds are provided.

The province's present revenue from its mining industry is being diverted to other purposes. About ten per cent. of it is used to maintain the Bureau of Mines. Little or none is used for roads and other such aids to mining development. True, last spring roads were promised for the new gold districts of northwestern Quebec; but these promises have since been "re-considered," and no roads are available. **Ninety per cent. of the province's income from mines is diverted to other purposes.**

Let us compare this with Ontario's practice, which has been successful in developing a mineral industry that today is prominent in the world of mining. Approximately one-third of the province's income from the mines is expended in administration, one-third is put into roads and other such aids to development, and one-third is added to the general funds as profits from a wasting resource. The third spent on maintenance supports a Deputy Minister and his statistical

staff; a Provincial Geologist, three permanent assistant geologists and half-a-dozen additional geologists during the summer months; a staff of draughtsmen; a Chief Inspector of Mines and three assistants; a Mine Assessor; a Mining Commissioner; and Mining Recorders in each of the numerous active mining divisions. The mining industry of Ontario is between two and three times the size of Quebec's; compare their administrative staffs. The opportunities for mineral development in Quebec are judged to be at least equal to those of Ontario. What use is the Quebec Government making of these opportunities?

The logical course of action is plain to see. The political administrators in Quebec must change their habit of obstructive parsimony to one of intelligent investment. They must add to the present starvation diet of the Bureau of Mines, that it may grow and flourish. They must provide an income sufficient to appoint a mine assessor, an adequate inspectoral staff, and a corps of first-rate geologists. Messrs. Denis and Dufresne are accomplishing wonders under their present appalling load of duties; but they cannot pretend to cope with the situation until they have the assistance mentioned above.

An adequately staffed Bureau of Mines at Quebec will work wonders in aiding not only the province's mineral development, but its rapid settlement as well.

THE VALUE OF WORK

By the use of the word *work* in these few lines we wish to connote the idea of *labor* — not a mere whiling away of one's time. There are some men who are said to "go to *work*" when they merely, with a pipe in their mouths, indulge in a little make-believe.

We noticed a man, the other day in Montreal, performing what seemed to us an astounding feat. He was standing on a ladder, and, apparently asleep, he was holding a paint-pot in one hand and a brush in the other. A passer-by informed us that he was working, from which we inferred that his work consisted in not falling off the ladder or not dropping his paint-pot or brush, for negative exertion of this kind was all that he was indulging in — "paid by the hour," as our friend, the passer-by, half enviously remarked. He himself, he said, was paid by the job, and, he added, as though it were a grievance, that *he "had* to work." In reality, instead of feeling aggrieved, he should have been thankful.

It is hard to understand why work should have been regarded as man's primal curse. It is really one of his most substantial blessings. There are few men, indeed, who have the strength of character to be beyond the necessity of work. And such men are generally the hardest workers of all. For the man who has sufficient moral stability for his character to be unimpaired by amplest leisure, is, nearly always curiously enough, as it seems at first sight — though, in reality, there is nothing strange about it — one who cannot bear to be idle. But he works without the propulsion of necessity. And it is, as likely as not, from this very circumstance, that his work derives not a little of its charm. He can choose his own branch of work. And, above all, he can choose public work or social work — work for others, and work the primary object of which is not to feed and clothe himself.

Take the case of Mr. Gladstone, for example. Born in a station of life, which rendered any professional or commercial labor on his part superfluous, with everything delightful surrounding him, he yet chose, for his portion in life, work — for others, it is true, but still work of the sternest sort. For he could do in four hours what it took another man a day to do, and he often worked fourteen hours a day! And yet he was exactly the style of man to whom dallying in a library, poring over classical tomes, and all the favorite aspects of that dignified ease, which most men of culture call work, the work of polished idleness, appealed with peculiar force. Indeed, they were his pastimes. For it is a mark of noble souls that, with them, work like life itself, must be treated as a thing that is real and earnest.

Still life is not all work, and work is not all life For our life should be our vocation, and our work should be our avocation, in the strict sense of that much ill-used word — our by-product, so to speak.

"Let me but do my work from day to day
In field or forest, at the desk or loom,
In roaring market place or tranquil room;
Let me but find it in my heart to say
When vagrant wishes beckon me astray,
This is my work; my blessing, not my doom;
Of all who live, I am the one by whom
This work can best be done, in the right way
Then shall I see it not too great, nor small,
To suit my spirit and to prove my powers.
Then shall I cheerful greet the laboring hours,
And cheerful turn, when the long shadows fall,
At eventide, to play, and love, and rest,
Because I know for me my work is best."

SMELTERS' GENERAL BRIQUETTE CORPORATION

Mr. Thomas F. Kelley of Buffalo, New York, has been appointed Manager of The Smelters' General Briquette Corporation specializing in the manufacture of briquettes for smelting purposes — notably from iron flue dust. The new corporation has been organized to succeed the metallurgical department of the General Briquetting Company.

Mr. Ellsworth B. A. Zwoyer of Perth Amboy, New Jersey, has been appointed Manager of The General Fuel Briquette Corporation organized to succeed the fuel department of the General Briquetting Company

Breaking Ground

An Interview with Mr. Nichol Thompson

Mr. Nichol Thompson has just returned from a visit to England. He was one of a delegation of 28 members of the Vancouver Board of Trade representing mining, timber, fishing, agricultural and general business interests, that went over to the Old Country with the object of breaking through the ice of reserve and getting down to a business understanding with the people of Great Britain.

To a man of Mr. Thompson's type, the opportunities thus presented for meeting the leaders of thought and enterprise, and discussing with them the vital questions affecting Empire development and improved relationships, were so important and pregnant with results, as to make the occasion of his visit a matter of public interest.

Mr. Thompson has lived thirty-seven years in Canada, he has been identified with every stage of progress in the West, and this life-work of his has been superimposed upon an intimate knowledge of Old Country traditions and methods, so that he is, to a very marked degree, in a position to voice opinion as to the requirements for mutual understanding.

Mr. Thompson says that as soon as it became known that each member of the delegation was defraying his own expenses, and that no one of them went over with any personal axe to grind, they were assailed by such a storm of enquiries, and found such a receptive attitude towards all the information they could give, as to show on the part of the people of Great Britain as keen a desire to open up, and interchange ideas as that with which they themselves were inspired.

The delegation was in Great Britain seven weeks, and during that period travelled over 2,500 miles. Very wisely the party did not split up into sections but travelled en bloc, thus emphasizing the unity of their purpose and their preparedness to deal with every point of view in the diverse communities that they visited.

Seven hundred individual interviews were held and altogether twenty-one thousand business men were met and addressed. Press recognition was received from over 600 British newspapers and more than 500 enquiries were answered daily. The tour was thoroughly organized, and regular meetings of the Executive Committee were held during the ocean voyage in order to provide for the greatest possible efficiency and team work.

Describing the tour, Mr. Thompson said:—

"The principal meetings commenced with the opening luncheon at the Empire Exhibition Building at Wembley. This luncheon was well attended and we had the honor of being the first public body entertained by the Committee of the Exhibition.

The following day, Empire Day, we were the guests at a luncheon given by the London Chamber of Commerce, and we also attended the Empire Day dinner at the Hotel Cecil, at which Lord Birkenhead presided. Our President, Mr. J. B. Thomson, and I had the honor of speaking.

Next morning we left for Bristol where we were met by the Lord Mayor and City Council, and entertained at luncheon, and were then taken over the Harbour improvements at Avonmouth.

This was the commencement of the provincial tour, during which we visited the Cities of Leicester, Birmingham, Manchester, Northampton, Liverpool, Edinburgh, Newcastle, York, Hull, Sheffield, and Nottingham.

On our return we had the honor of being received by H. R. H. the Prince of Wales, who talked at length with each member of the delegation, and showed the greatest interest in and sympathy with our work and aims. After this reception we motored down to Petersham, and our Native Sons planted seeds of British Columbia trees near the grave of Capt. Vancouver. The First Lord of the Admiralty was present and gave an interesting address.

Large meetings were held and addressed at all the places mentioned above, and we visited many important industrial works, including the Small Arms Factory at Birmingham, Cadbury's Cocoa Works, the Manchester Ship Canal and Terminal Docks, the Midland Car & Wagon Works at Birmingham, the Textile Works at Leicester, the large factories at Nottingham, also Cammell Laird's Railway Equipment Works there, and Vicars Steel Works at Sheffield.

Every effort was made by our hosts to make our tour interesting, and to enable us to gain the best possible insight into conditions of life in Great Britain.

We were motored to Chatsworth, the seat of the Duke of Devonshire, and out to the historical Haddon Hall, and

Mr. Nichol Thompson.

we visited the old Castle at Edinburgh and Hollyrood Palace, and in this city we were entertained at lunch by the Chamber of Commerce, and by the Lord Provost at dinner.

At Newcastle the Lord Mayor and Sheriff showed us every attention, and so it was at every city and town that we visited,—our reception was most cordial. At all our meetings and interviews there was a free interchange of ideas, especially in regard to the best way to stimulate trade within the Empire, and the people generally evinced a very receptive attitude towards our own expressions of opinion.

We discussed at length the question of the better distribution of population, the surplus population of the British Isles, and the surplus acreage in the Overseas Dominions. This was a subject that has evidently been engaging the interest and attention of all classes in Great Britain,—indeed we found very little need for urging a closer attention on the part of the people in the Old Country to the possibilities of the Overseas Dominions, and among the many who showed a keen desire for closer connections we were impressed particularly by the keenness and sincerity of Lord Birkenhead, the Duke of Oevonshire, Mr. Joynson Hicks, Lord Long of Wraxall, and the Premiers of Australia and New Zealand. We came away with the conviction that the key-note for better mutual understanding of one another's point of view is to be found in a closer trade relationship and in the merging of interests, and that all that is required for this purpose is to familiarize people with the facts.

The British capitalist only requires to be shown the importance of establishing works by means of which the natural resources could be manufactured into such shape as would allow of their being shipped at a profit to Great Britain. He already wants to do this; to import semi-manufactured goods that may assist the export trade of Great Britain in finished products. It is important also to encourage the idea of human relationship. What is clearly needed is to get the people of Great Britain imbued with the idea that they themselves, as well as we, are part of the great British Commonwealth, and that when they leave any part of the British Isles for another part of the Overseas Dominions, they are not emigrating or immigrating but simply moving from one part of the country to another. We felt very strongly, as the result of our most interesting tour, that in the encouragement of this feeling we may arrive at the true spirit of human brotherhood that is the highest bond of Empire."

Mr. Thompson was able to point to two practical results of the tour, namely, the inauguration of two new lines of steamers running direct from Bristol and Manchester respectively to Vancouver.

The interests of the mining industry of British Columbia were in the special care of Mr. Thompson, and at his hands they were well served; there was no attempt to force individual attractions upon attention, but rather the policy was adopted of inspiring the thought that British Columbia must be a country with great mineral possibilities, and the interest to ask where and what they are. That success was achieved in the endeavour is evidenced by the fact that the last week of Mr. Thompson's stay was entirely occupied by interviews with all kinds of business men in London to the exclusion of all other prearranged business.

As compared with what he knew twenty-five years ago Mr. Thompson was impressed by the improvement in conditions generally in Great Britain, by a general elevation of thought and expansion of ideas, and an atmosphere of reciprocity in which one may look for a rapid growth of understanding, confidence and goodwill. This is the prime need of the mining industry of British Columbia to-day, and in fostering it,—the delegation of which Mr. Nichol Thompson was a member has earned the country's gratitude.

IMPORTANT APPOINTMENT BY B. E STEEL CO.

The British Empire Steel Company have appointed Frank Lucas head of the department for the sale of coke. This is one of the most important steps ever taken in the history of the Canadian Coal industry and will be watched with intense interest from far and near. To supply the anthracite market of the Maritime Provinces and of Quebec it is the object of the Steel Company. Like all new projects it will at first have a small beginning, but there is no doubt in the minds of those interested in the coal industry but that it will eventually succeed. The quality of the coke supplied may not at first be quite suitable to domestic use, owing to the present construction of the ovens, but it is stated that even with the ovens built for metallurgical purposes a fair quality of coke for domestic use can be supplied. Mr. Lucas is the right man in the right place for he has had considerable experience and a long training in the work of analysing coal, coke and other minerals. He is intensely interested in the work, and we look forward to much progress both in the making and the sale of coke, from Cape Breton coal.

BRICKS FROM OIL SHALE

With the object of obtaining a product cheaper than the ordinary clay brick, experiments have been made in Germany in the manufacture of bricks from oil shale, of which there are large deposits in various parts of the country.

One process that was tried depended on mixing the shale with cement or lime and subjecting it to hydraulic pressure. The result, however, was not entirely satisfactory, because it was found impossible to attain uniformity of quality, owing to the varying contents of lime and pyrites. This process was accordingly abandoned in favour of another which has been tried successfully at the Prussian Geological Institute and at several brickworks. The shales, after the pyrites has been separated from them by sifting, are ground up with a proportion of clay or sand which varies according to the richness of the shales, and the powdered mixture is then moulded into bricks, which are put straight into the kiln without being dried. No fuel is required to burn them, as the inherent content of oil in the shales suffices for that purpose. Bricks made in this way are said to be slightly lighter in colour than ordinary bricks, but to be no different in appearance otherwise. A mixture of oil shale and clay has given bricks which contain only small amounts of calcium sulphate and sulphite and can stand a pressure exceeding 1,000 lb. per sq. in. Their strength is thus sufficient for ordinary house-building, and may, it is thought, be increased by improvements in the process.—Ex.

PERSONAL

Mr. James Bartlett, who has been with the Ontario Department of Mines since 1914 as inspector of mines, resigned on September 1st to become associated with the Coniagas Mines at Cobalt. Mr. Bartlett at the time of his resignation was in charge of the Sudbury district.

Natural Gas and Petroleum Resources of Western Canada

Recovery of Natural Gasoline by the Charcoal Absorption Method

By NEWTON W. EMMENS

The most recent development and improvement in the recovery of gasoline contained in natural gas is the use of activated charcoal as the absorbent medium in place of oil. By this improvement not only is the operation of the plant simplified, but the percentage of recovery is greatly increased.

The Discovery of Activated Charcoal

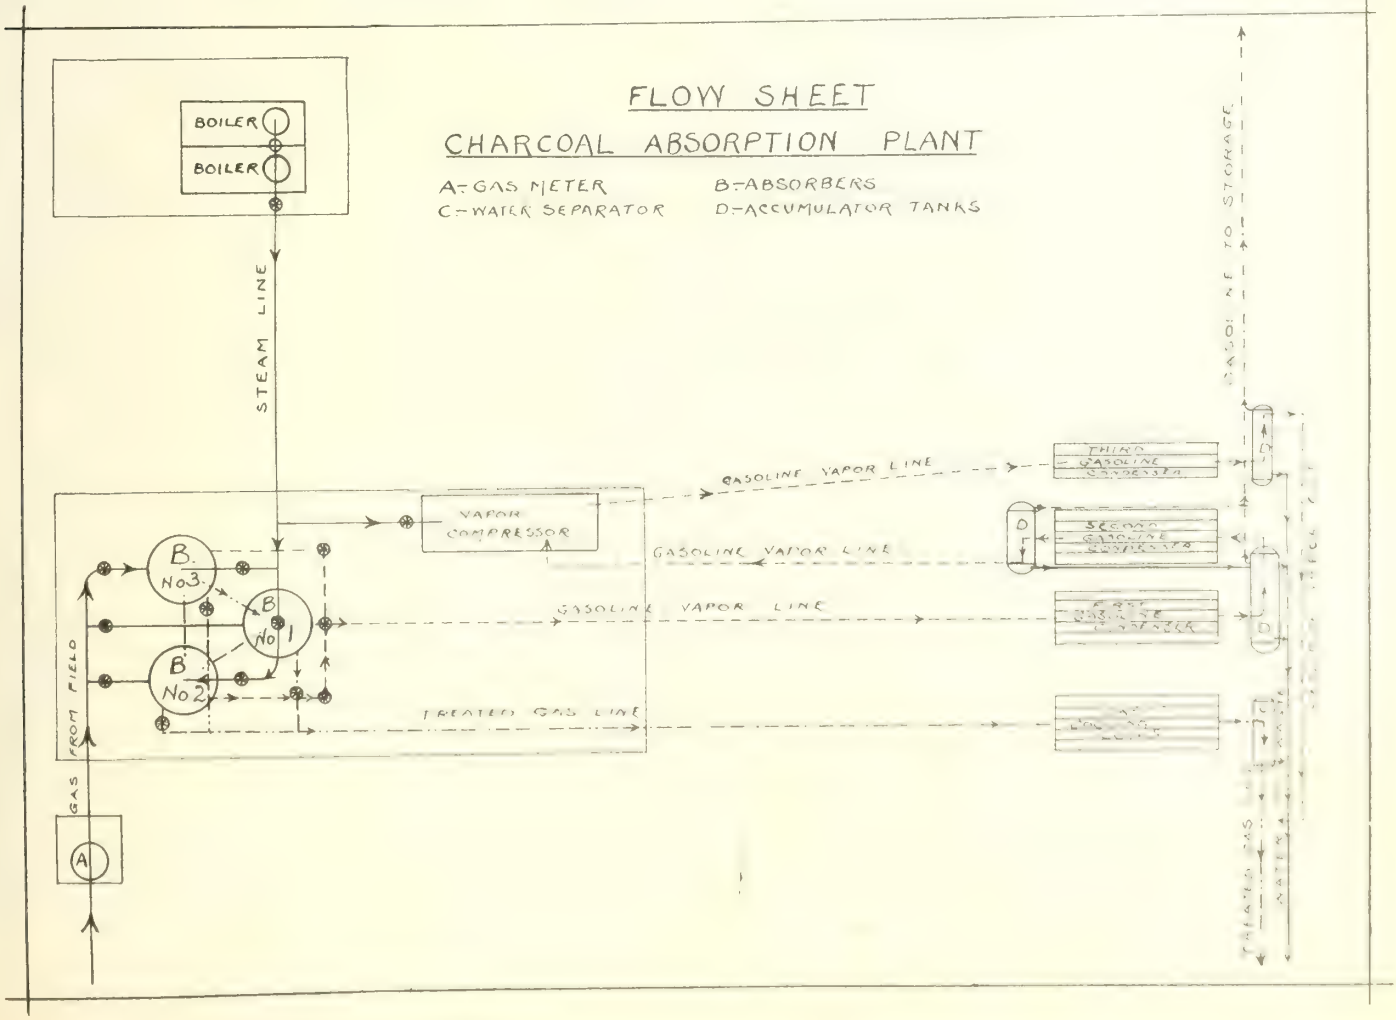
The charcoal used in this process is manufactured by a long and complicated process from cocoanut shells to meet the particular requirements of gasoline absorption and is subjected to a series of laboratory tests before being approved for use in the commercial plant. The charcoal is crushed into pieces about the size of wheat grains and has the power of absorbing, through the microscopic capillaries each grain contains, liquids and gases. There are several types and grades of activated charcoal on the market, but one type has been found to make the greatest recovery of the gasoline contained in natural gas. This particular type of activated charcoal will absorb 15 to 20 per cent. of its own weight in marketable gasoline.

The development of the charcoal absorption process is the result of investigations, carried out by G. A. Burrell and G. G. Oberfell during the war, concerning substances that could be used in gas masks for absorbing poisonous gases. Since the close of the war the investigations have been continued and the knowledge obtained has been put into practical use for the treatment of natural gas. Its commercial application, and the development of the plant details are due to the work of C. L. Voress, V. C. Canter and R. W. Skoog.

Data Obtained by Testing

To obtain the data necessary for designing the plant, the gas to be treated must be accurately measured, and analyzed and its gasoline content determined by means of absorption with the same type and grade of charcoal to be used in the commercial operation, because upon the density of the gas, its velocity, latent heat, and gasoline content depends the size of the absorber and the internal arrangement. The apparatus required to make these tests is very much simpler, less expensive, and more easily carried from place to place than that required for tests by either the compression or oil absorption method described in my previous article. It consists of an effusion apparatus for taking the gas density, a Pitot tube, a gas meter, a U tube, absorbers filled with charcoal, and a stop-watch.

The determination of the gas density by effusion is based upon the fact that the times required for the escape of equal volumes of two gases under the same pres-



sure, through the same small orifice, are approximately proportional to the square roots of the densities of the gases. The densities, or weights, are therefore proportional to the square of the times of effusion. The specific gravity of a gas is the ratio of the weight of a given volume of the gas to the weight of an equal volume of air, measured at the same temperature and pressure. The apparatus used by the author is known as the "Schilling Apparatus" and consists of a glass jar 3 1-2 inches in diameter by 12 inches deep, closed by a brass cap through which is inserted a graduated glass tube, one inch in diameter. This graduated tube is mounted in a brass casing, slotted for the observation of the water column, and capped with a three-way cock and small protected glass tip into which is fused an orifice plate made of platinum-iridium alloy.

Gas Density Test

The method of making a test is as follows: The large glass jar is filled with clear water to just above the upper graduation on the inner tube. This tube is then filled with air and the three-way cock opened so as to allow the air to escape through the little orifice plate in the glass tip, and the number of seconds required for the water level to rise from the lower to the upper mark in this tube is carefully noted. This test should be repeated several times and the average of the readings taken as the time required for the air to pass through the orifice plate. Having done this, the next step is to connect the side opening of the three-way cock with the gas supply, by means of a rubber tube. The gas is then turned on carefully and allowed to expel the water from the inner tube and bubble up through the water in the outer jar, letting it run for several minutes so as to be sure that all the air in the inner tube has been replaced by gas. The three-way cock is then turned so as to shut off the gas supply and allow the gas in the inner tube to escape through the little orifice, and the time that it takes the water to rise from the lower to the upper mark is carefully noted, as was done in making the air test. Repeat this several times and record the average as the time required for the gas to pass through the orifice. Square these two results and divide the gas time by the air time, the result being the specific gravity of the gas, air being one. For example, if it took 160 seconds for the air, and 129 seconds for the gas to pass through the orifice, we should have 16,641 (square the gas time) divided by 25,600 (square of the air time), which gives us 0.650, the specific gravity of the gas as compared with air.

Apparatus for Absorption Test

The specific gravity of the gas is required in order to know how many cubic feet to pass through the little absorber in making the test for its gasoline contents, because the correctness of this method of testing depends upon the saturation of the charcoal, which should be such that on distillation about 25 cc. of gasoline are recovered. For example, a gas tested by the writer, having a specific gravity of 0.82, yielded 25 cc. of gasoline from the charcoal after 10 cubic feet of the gas had been passed through the absorber, while a gas having a specific gravity of 0.64 required the passing of 35 cubic feet through the absorber before the charcoal was saturated sufficiently to yield 25 cc. on distillation.

The charcoal absorbers used in testing natural gas consist of a metal tube 1-⅛ inches in diameter by 10 inches long, containing a perforated disc fitted inside the tube near one end, and closed at either end by a screw cap. The absorber is filled with activated charcoal of the proper type and grade, which must be perfectly dry, as the presence of moisture impairs the ability of the charcoal to absorb gasoline vapors.

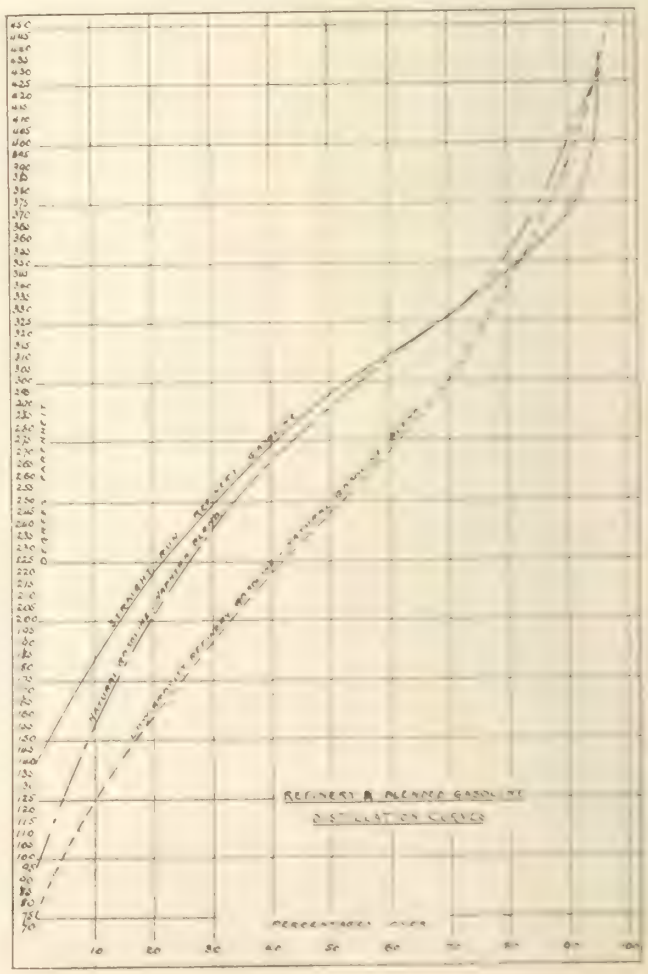
The Absorption Test

In making a test, the gas from the well first passes through the meter and then through the little absorber, at atmospheric pressure and at a speed of about twenty cubic feet per hour, until the estimated quantity has been passed, after which the absorber is disconnected, capped, and taken to the laboratory, where the gasoline is distilled off and measured. When testing gas in a new field it is well to make several absorption tests, one using the estimated quantity of gas based on its specific gravity, and others using greater and smaller quantities, taking as the correct result the number of feet yielding gasoline, on distillation, closest to 25 cc., and from it calculating the gasoline content of the gas.

The charcoal testing method shows a greater yield of gasoline than any other direct testing method, when the tests are properly conducted with the correct grade of charcoal, but it does not show the maximum saleable product recovered when the gas is treated in a charcoal absorption plant.

Commercial Absorption Plant

The commercial plant consists of meters for measuring the gas, absorbers, condensers, accumulator tanks, vapor compressors, storage tanks, steam boilers, electric light plant, pumps for supplying the water for the boilers and condensing coils, chemical fire extinguishers, laboratory, and, in some installations, a blending tank. In these plants three absorbers are used alternately so that while one absorber is being charged with gasoline, the second is having its gasoline content distilled off, and the third is having its charcoal cooled preparatory to re-charging with gasoline.



The cycle of operation in these absorbers is as follows: Assuming that No. 1 absorber has just had its gasoline distilled off, that No. 2 is charged with gasoline and that No. 3 is ready to be charged; then the gas as it comes from the field is turned off from No. 2 absorber and into No. 3, steam is turned into No. 2, and the gas as it comes out of No. 3, being denuded of its gasoline, is turned through No. 1. The steam, on coming in contact with the charcoal, partially condenses, and drives out the gasoline that has been absorbed, replacing it with water vapor at a high temperature and at the pressure of the steam.

The vaporized gasoline and some of the steam pass on to the condensing coils. After the gasoline has been driven out, the charcoal is hot and filled with water vapor, so it is necessary to cool it and get rid of this water before the charcoal will be in a condition to absorb a fresh charge of gasoline vapor. This is accomplished by means of the treated gas which, while being stripped of its gasoline vapors, still contains ethane, propane and some butane that are not condensed to a liquid at the temperature of the gas, and at atmospheric pressure. This gas, on coming in contact with the hot charcoal, cools it, replacing the absorbed moisture with hydrocarbon gases, so that at the end of the cycle the charcoal is at the temperature of the flowing gas, has its capillaries filled with it, and is ready to absorb another charge of gasoline. This treated gas, together with the moisture taken up from the charcoal, goes to a cooling coil where the water is precipitated, thence through a separating tank and into the gas lines leading out of the plant.

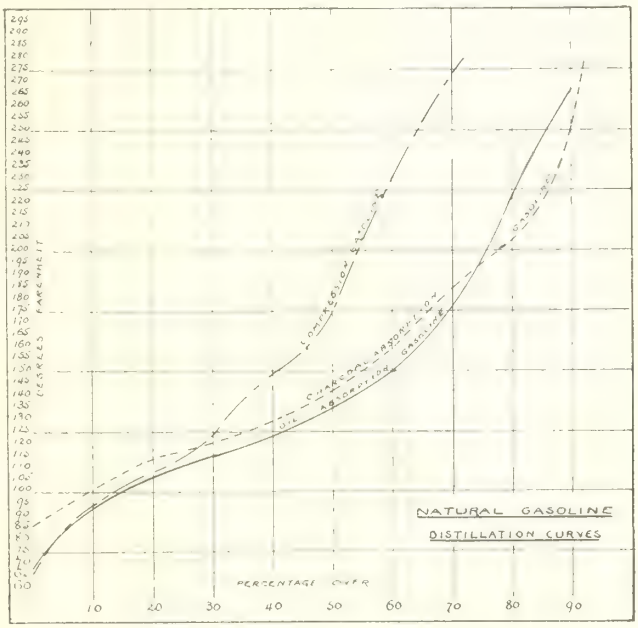
Separation of Gasoline and Water Vapor

The steam and gasoline vapor from the absorber being distilled go to the first condensing coil, where all the water and some of the gasoline are condensed. The condensate goes to an accumulator tank where the water and gasoline are separated, the former going to waste and the latter to the storage tanks. The uncondensed vapors from this first condensing coil go to a second, where they are subjected to a lower temperature and additional gasoline is recovered. From here the residual vapor goes to the compressor, where its pressure is raised, and thence to the third set of coils where the remaining condensable gasoline vapor is recovered.

The efficiency of the charcoal plant is high, and it is commercially practicable to recover 100 per cent. of the gasoline contained in the gas, and, owing to the selective absorption properties of the charcoal, the quality of the product can be made to conform to the requirements of the market, without sacrificing efficiency, which cannot be done with the other processes.

Blending of Natural Gasoline

The gasoline obtained from natural gas by the processes described is not so well suited for use in gasoline engines (except for aviation purposes) as that made by the distillation of petroleum, because natural-gasoline contains a larger proportion of the low boiling-point fractions and a smaller proportion of the high; consequently the vaporization losses while the liquid is in storage are high, particularly in a hot climate. To overcome this difficulty the natural-gasoline is mixed with either naptha or low-gravity refinery gasoline. These mixtures, if properly made, yield a gasoline admirably suited for use in motor cars, and by varying the proportions of the natural gasoline and blending material, a motor gasoline can be produced that will give the maximum power under any climatic conditions. For example, in a country where the temperature never falls below 60 deg. F. and goes above 100 deg F., a gasoline having an initial boiling point of 140 deg. F., and an end point (that is the temperature at which the last drops distil) of 437 deg. F. is an excellent motor fuel, with reasonable storage losses; but such a gasoline would not give good results in a cold climate because of the difficulty of starting the engine without pre-heating. A natural-gasoline blend, however, with an initial boiling point of 95 deg. F. and an end point of 428 deg. F. makes a very satisfactory material, and a cold automobile engine will start readily on such a fuel even in zero weather. The accompanying curves from the distillation of gasolines and blends (made in accordance with the recommendations of the U. S. Bureau of Standards) show graphically the volatility of each.



Type of Buildings Required

In the treatment of natural gas for its gasoline content, temperature plays an important part with the oil absorption process, not only in regard to the percentage of extraction but also in regard to the quantity of gas used for heat and power purposes, and in the circulation of the absorption oil. In a country where the winter temperatures are low, such as in Alberta, particular attention should be paid to the type of buildings erected for the housing of the machinery and in the insulation of the absorbers, oil storage tank, vent tank, still, and oil lines, because the absorption oil becomes quite thick when chilled, making it difficult, and often impossible, to circulate satisfactorily. This, of course, adds to the expense of installation.

The charcoal process is not open to the same objection, because there is no oil to circulate and the absorbers, being comparatively small, do not require as much insulating material nor material of such a high grade, because they are housed within a building.

The type of building used depends upon the location of the plant, but it should of course be as nearly fire proof as possible and should be warm in winter and cool in summer. If sand and gravel can be obtained locally at a reasonable price, there is nothing better than a reinforced concrete building of the Van Guilder type, which is essentially a double-walled structure with an air space enclosed between the walls. No special forms are needed for this type of structure, nor is skilled labor required, as anyone who can handle a shovel and a tamping rod can do a very satisfactory job. The building is roofed with steel pur-

The Author testing natural gas for gasoline by the charcoal absorption method, at a gasoline plant in West Virginia.

lins and either corrugated iron, or asbestos sheets, preferably the latter.

Another type of building is the sectional iron structure, lined with some non-inflammable material such as plaster board.

Cost of Buildings

With cement costing $3.10, per barrel, sand $4.70 per yard, and gravel $4.55 per yard, delivered at the site where the buildings were erected, and with labor at $3.50 to $4.50 per day of nine hours a building 20 ft. × 25 ft. of the double-wall concrete construction cost, complete including floors, $1,388, as against $1,458 for a sectional steel building of the same dimensions, but unlined.

The only argument in favor of the sectional steel building is its salvage value after the gas field has become exhausted, which would be about 20 per cent. at the end of ten years if the buildings has been kept properly painted and reasonably cared for. Against this salvage value for the steel building is the saving in fuel for heating, the increase in the efficiency of the plant due to uniformity of temperatures, savings in general repairs and painting, and lessened insurance costs in favor of the concrete structure.

Cost of Absorption Plant

It is not possible to give an exact estimate of the cost of an absorption plant in Alberta without knowing labor costs, freight rates, duty, the cost of hauling and excavating and other items that are governed by local conditions, but it would probably be between $130,000 and $160,000 for a plant to handle 10,000,000 cubic feet of gas per day containing 500 gallons of gasoline per million cubic feet, thus providing an output of 5,000 gallons per day of marketable gasoline.

To operate such a plant would require nine operators, using eight-hour shifts with three men on a shift, in addition to a chemist, one man to load tank cars and generally to help at odd jobs, and a superintendent. Allowing for good wages and salaries (considerably higher than is being paid in the United States) and an ample allowance for supplies and minor repairs, the operating expense would not exceed $3,000 per month.

Value of Gasoline Recovered

The output from such a plant would be 150,000 gallons of gasoline monthly, worth about 15 cents per gallon under normal conditions, or a total of $22,500. At present, owing to the temporary over-production of crude oil and gasoline, the market price of natural-gasoline is about 8 cents per gallon, which would make such a monthly output worth $12,000. These figures are based upon the supposition that the gas cost the plant nothing; that is, that the owners of the gas field built the plant and after extracting the contained gasoline, sold the residual gas or manufactured it into some article of commerce, such as carbon-black. If the plant were charged up with the value of the gas converted into gasoline and burned in the operation of the process, such expense would be added to the $3,000 monthly operating cost. Making ample allownace for leaks and sundry losses, this would require approximately 10,000,000 cubic feet of gas monthly for an output of 150,000 gallons of gasoline, and this at 8 cents per thousand cubic feet would be worth $800, making a total expense of $3,800.

So far as the gas fields of east central Alberta are concerned the important problem is to know what to do with the gas after extracting the gasoline, as there is no domestic, or industrial market for it, nor can there be for many years to come. Such a market requires a large urban population. Nevertheless, it cannot be allowed to go to waste by blowing it into the air.

To make carbon-black from it is one solution, which will be discussed in the next article.

PETROLEUM PARAGRAPHS

The McMurray Asphaltum & Oil Co., Limited, is developing actively its tar-sand properties near McMurray on the Athabaska river. From the bitumen extracted from this sand a paint is being manufactured which is particularly suitable for protecting iron and steel from rust. It is to be used to paint the gas pipe-line now being laid from the Viking field to Edmonton, Alberta.

In addition to extracting bitumen, the McMurray Asphaltum & Oil Co. are recovering an oil from this tar sand, of 19 deg. Be. gravity. The sand contains: gasoline 5 per cent.; kerosene 3 per cent.; gas oil 28 per cent.; lubricating oil 44 per cent.; asphalt residue 20 per cent. The oil contains some sulphur, which is giving a little trouble in the producing of a satisfactory water-white kerosene, but this difficulty will be overcome in due course.

It is believed that the products of these tar sands will ultimately displace the asphalt now imported from Trinidad and willl be increasingly used for road making in Canada. Tests are now being made by the University of Alberta on the utilization of this material for road building, with most encouraging results.

From the Fort Norman field it is reported unofficially that the discovery well is now good for 75 barrels of oil a day, and that the well is shut in at present so as to conserve the oil until such a time as it can be used. The results of the drilling of the Bear Island and "C" camp wells are said to be encouraging, both wells showing oil but no large production.

Sufficient work has been done in the Fort Norman field to prove the existence of oil in large quantities; but under present conditions of transportation and oil prices

it cannot be made of commercial use and the tremendous expenditure necessary to provide a means of bringing the oil out is not justified at present. It is, however, a good thing to have it in reserve and to know that the oil is there when needed.

In the Sweetgrass section of southern Alberta the Imperial Oil Company's well in Sec. 5, Tp. 1, R 16, west of the 4th mer., has been drilled to a depth of 2,700 feet without getting oil in commercial quantities, although it was carried through the Madison sands. The well is to be abandoned and the casing pulled. In other sections of the Sweetgrass district "shows" of oil are reported in the drilling wells, but not in commercial quantities, thus far. Drilling still continues.

In east centel Alberta the well drilled near Birch Lake, in Tp. 50, R. 12, west of the 4th mer., is reported to have struck a commercial flow of oil at a depth of 2,200 feet.

In the Irma-Wainwright field the No. 2 well of the British Petroleums is drilling at 1,600 feet and the No. 2 Grattan of the Imperial Oil Co., at 2,000 feet.

The Irma Oil Development Co. have finished their water well and are drilling for oil and gas in Sec. 28, Tp. 45. R. 9, west of the 4th mer.

In the Viking field the work of connecting up the wells and the laying of the pipe-line to Edmonton is making good progress. Deliveries of pipe are being made promptly, much of it coming from Great Britain by way of the Panama Canal and the port of Vancouver.

Canada's New Patent Act

An Explanation of the Important Changes

By H. MACDONALD, Legal-Secretary, Canadian Manufacturers' Association, in "Industrial Canada."

Manufacturers' Association, in "Industrial Canada."

The new Patent Act enacted in the last session of the Dominion Parliament, and which by proclamation of the Governor-in-Council came into force on Sept 1st, 1923, contains many provisions radically different from those in the old Act. The principal changes have to do with the conditions an applicant must fulfil in order to obtain a patent, and with which he must comply in order to maintain his patent in force. The prohibition against importation of the patented invention after one year from the date of the patent is removed and new manufacturing and licensing provisions introduced.

The former Patent Act, in its main provisions, has remained substantially unchanged since 1869, when it was drafted, with the United States Act of 1836 as a model. Since that date, the only material change that has been made has been the introduction in 1903 of the compulsory license system as a substitute for workings with respect to certain classes of inventions.

The International Convention

There has been a growing sentiment that the Canadian Patent Act should be amended in order to permit Canada to become a member and so secure the advantages of the International Convention for the Protection of Industrial Property (signed at Paris, March 30th, 1883; revised at Washington, June 2nd, 1911). The principal advantage to be obtained by the Convention is that contained in Article 4 thereof, which provides: "Any person who has duly applied for a patent, industrial design or model, or trade mark in one of the contracting states shall enjoy, as regards registration in the other states and reserving the rights of third parties, a right of priority during the periods hereafter stated."

The period stated with respect to patents is one year. Canada under its former Act, gave the same protection as the Convention did to all foreign applicants, but received nothing in return. The principal bar to Canada hitherto becoming a member of the Convention has been that contained in Section 38 of the former Patent Act, which prohibited importation after one year, this being contrary to Article 5 of the Convention.

The revision of the working requirements contained in the new Act will enable Canada to become a member of the Convention, with the result that inventions by Canadian inventors will be protected during a period of one year in all countries of the International Union. These countries include, at the present time, Austria, Belgium, Brazil, Cuba, Denmark, Dominica, France, Germany, Great Britain (with Australia, Ceylon, New Zealand, Trinidad, and Tobago), Holland, Hungary, Italy, Japan, Mexico, Norway, Portugal, Serbia, Spain, Sweden, Switzerland, Tunis, and the United States.

Revised Conditions

The conditions imposed on an applicant for a patent have been revised in the new Act as follows:

"7 (1) Any person who has invented any new and useful art, process, machine, manufacture or composition of matter, or any new and useful improvements thereof, not known or used by others before his invention thereof and not patented or described in any printed publication in this or any foreign country more than two years prior to his application and not in public use or on sale in this country for more than two years prior to his application may, on a petition to that effect, presented to the Commissioner, and on compliance with the other requirements of this Act, obtain a patent granting to such person an exclusive property in such invention.

"(2) No patent shall issue for an invention which has an illicit object in view, or for any mere scientific principle or abstract theorem."

The principal changes are (a) with respect to prior knowledge in other countries than Canada; (b) with regard to prior publication; (c) with regard to public use or sale prior to application.

Former Act Rigorous

Under the former Act the requirements which an applicant for a patent had to fulfil with regard to prior knowledge were more rigorous than any other country in the world. To be entitled to a patent in Canada, under the former law, the applicant had to be the first inventor throughout the world, and not merely in Canada. This made a Canadian patent liable to attack

by proving that, prior to the date of the alleged invention, it was, as a matter of fact, known in some way to some other person in some other part of the world. The phraseology of the former Act was particularly comprehensive in requiring that the invention should not be "known or used by any other person before his invention thereof." The new Act substitutes "not known or used by others in Canada before the invention thereof." By the new Act, not only is knowledge restricted to Canada, but it is required to be knowledge "by others," not "by any other person." This phraseology has been construed in the United States courts to exclude secret knowledge, such as an unpublished drawing or prior model.

The new Act makes publication for more than two years in Canada or any foreign country a bar to the application for a patent.

The new Act also introduces a prohibition against public use or sale in Canada for more than two years, and makes no reference to whether or not the public use or sale was with the consent or allowance of the inventor or not.

Section 8 of the new Act extends the time within which application may be made on an invention for which a foreign patent has been taken out until two years from the date of application of the foreign patent, as compared with one year from the date of issue in the former Act. The corresponding section in the United States permits application within one year from the date of application in a foreign country, for which protection is afforded by the International Convention.

Explanations of Sections

Section 16 contains new law and follows exactly the terms of Section 11 of the British Patents and Designs Act, 1919. It provides, in brief, that in the case of patents on chemical processes no claims shall be made for the substance itself except when prepared by the special process described, and further, that in the case of inventions maintained for the preparation or production of foods or medicines, the Commissioner may grant a license to any person applying for the same, upon such terms and conditions as may be settled by him, having regard to the desirability of making the food or medicine available to the public at the lowest price consistent with giving to the inventor due reward for the research leading to the invention. The enactment of this law in Great Britain is too recent to enable any opinion to be formed as to its effect.

Section 24 introduces new law with regard to invention made by persons in public service, and is a restriction upon the rights of such persons.

Section 27 of the Act, with respect to the re-issue of patents, has been amended, but limits the time within which application for re-issue should be made to four years from the date of the patent.

Section 40 sets out the specific conditions under which any patent, except those governed by Section 24, is subject, respecting the manufacture of the patented article, for the reasonable requirements of the public, all questions regarding which may be determined by the commissioner or on reference to the Exchequer Court.

The right of the Government of Canada with regard to a patented invention is covered by Section 48, which reads: "The Government of Canada may, at any time, use any patented invention, paying to the patentee such sum as the Commissioner reports to be a reasonable compensation for the use thereof, and any decision of the Commissioner under this section shall be subject to appeal to the Exchequer Court.

Summed up briefly, it may be said that the provisions of the new Act are more liberal in the consideration extended to inventors. Amongst the most important departures from the old legislation are extension of the time limit set for the manufacture of the patented device; provision for one partner in an invention to secure a patent upon it under certain conditions; making registration of patent attorneys obligatory, and reducing the amount of fees, and the danger of allowing the patent to lapse through failure to pay a second fee instalment. Inventors and manufacturers will thus be given a better opportunity to develop inventions to a commercial stage than under the rigid manufacturing and importation requirements of the old Act, and in the end Canadian industries will be benefited more by the resulting commercial development than by any advantages formerly obtained from forfeiture.

PLATINUM AND PALLADIUM AT SHEBANDOWAN

In *Summary Report*, 1922, *Part D*, of the Geological Survey there is a short report by T. L. Tanton on the nickel deposits at Shebandowan Lake, 50 miles west of Port Arthur, on the Canadian National Railway. The deposits are held by J. C. Cross of Port Arthur, who described them in the *Canadian Mining Journal* on May 5th, 1922. At that time Mr. Cross suspected the occurrence in the ore of metals of the platinum group, having obtained reactions in qualitative tests that clearly indicated their pressure. However, he was unable to obtain official confirmation of the fact. Since that time analyses made by the Mines Branch, Ottawa, have determined in fair samples of the ore, platinum from 0.2 to 0.4 ounces per ton, and palladium from 0.08 to 0.12 ounces per ton. The samples contained from 0.04 to 5.95 per cent nickel and a relatively large amount of insoluble material. These results indicate that there is a relatively high content of platinum group metals in the deposits and that, as far as known, these occur almost uniformly in the wider ore bodies along the whole length of the deposits, a mile in extent.

The deposits, as described by Dr. Tanton, are a type of replacement deposit in Keewatin schists and associated acidic dykes, parallel to a huge granitic batholith and at a distance of 50 to 150 feet away from it. Part of the schist is an altered peridotite, and it is in this peridotite that the lenses, filaments and irregular masses of sulphide minerals occur. The deposits have been uncovered in trenches in the rock, so that widths rather than lengths have been determined. The largest body so far opened up has a width of 19 feet. As the sulphide-bearing rock has been deeply weathered, it has been difficult to outline the deposits.

Regarding the origin of the deposits, Dr. Tanton found evidence that it is magmatic, and that the mineral-bearing material was derived from an intrusion later in age than the granite batholith.

New Survey From Kitsault River to Skeena River

Dr. George Hanson's Reconnaissance of 95-mile Strip along Coast Range Batholith

In pursuance of its stated policy to aid and direct the prospector, the Geological Survey maps each year promising mineral-bearing areas. In British Columbia last year George Hanson made a reconnaissance of a 95-mile stretch along the east flank of the Coast Range batholith. An interim report is published in **Summary Report, 1922, Part A,** from which the following paragraphs, of economic interest, are abstracted:

During the field season of 1922 the writer carried on a geological reconnaissance in the area between Kitsault river and Skeena river. The area reconnoitred embraces the Alice Arm district and extends south-southeast, as a narrow belt which crosses Nass river at Aiyansh. From this point, it lies in the drainage basins of Tseax and Kitsumgallum rivers and eventually reaches Skeena river at Terrace. The possibility of the discovery of petroleum in commercial quantities in Kitsumgullum valley was to be investigated, and a general idea of the economic geology of the whole area was to be obtained. Although the contemplated reconnaissance was not finished, some information was obtained and is enbodied in the present report.

General Geology

The rocks in the area are in the main of Jurassic age. They have been severely folded in most places and intruded by granitic rocks of the Coast Range batholith, which now forms the western border of the area. The region to the north, east, and south, immediately adjoining the area, has not been explored geologically. The Jurassic formations are overlain by Cretaceous sedimentary rocks which have been intruded by granitic dykes and stocks. Unconformably above the Cretaceous lie isolated patches of Tertiary sedimentary rocks and lava flows. Pleistocene glacial debris is found locally; recent gravels and clays are found along the main valleys; and a recent lava flow perhaps 300 years old is present in the central part of the area.

The area under discussion lies along the eastern border of the Coast Range batholith. It is 95 miles long, and, naturally, contains several types of mineral deposits. Most of those in upper Kitsault valley have been described recently, and will not be again described here. The mineral deposits could be divided into groups on a basis of form or mineral content, but it is more convenient here to describe the few that were examined according to the locality in which they occur. All of them were formed by ascending mineral-bearing solutions emanating from some underlying source—probably the Coast Range batholith and associated outlying stocks. In a few instances the primary mineral deposits thus formed have been modified by supercial agencies. In addition to metallic mineral deposits, coal seams occur in the area.

Alice Arm District

This district has undoubted economic possibilities. The mining of high-grade silver ore appeals to the prospector, because ore can be mined with practically no outlay of capital. A prospector cannot, however, afford to build wagon roads, or even pack trails, for the purpose of taking out his ore; consequently, wagon roads through the more promising mining districts would be of very great aid.

Mining might also be carried out on a moderately large scale, and lower grades might be used, if the ore were concentrated instead of being shipped direct. This might be done by a company controlling several properties within easy reach of the mill. There are a few properties with good surface showings and others where hopes of discovering good ore seem well founded. A few of these properties may develop into mines.

Excepting the properties in the upper Kitsault valley described last year, only two properties in the Alice Arm district have shipped ore. These are the Esperanza and the La Rose. The La Rose has made two shipments amounting to 33 tons, carrying 0.12 ounces gold and 235 ounces of silver per ton. The Esperanza has made small shipments for a number of years, the ore containing up to 0.2 ounces gold and about 200 ounces silver per ton.

Properties on Northeast Fork of Kitsault and Illiance Rivers

On the northeast fork of Kitsault river the San Diego and Red Bluff properties lie in a fine-grained grey rock apparently of sedimentary origin, but similar in many ways to the "copper belt" rocks farther north. The properties farther upstream lie in sedimentary rocks that are chiefly argillites of the Jurassic sedimentary series.

On upper Illiance river the tuffaceous sediments and tuffs have a north to north-northwest strike. On the east and also on the west side of the river the rocks dip gently to the west, but in a zone which is followed by the stream they dip steeply to the west. There appears to be a sharp flexure in the formation, the west side having moved downward in relation to the east side. Along the flexure the rocks are sheared and along this sheared zone ore solutions have ascended and formed a number of mineral deposits. The Bellevue, United Metals, Silver Bell, and half a dozen other mineral properties, have been staked along this zone. The mineral zone is strongly defined and may contain rich and perhaps extensive shoots of ore. The mineralization is of the silver-lead type. The Monarch is one of the few properties which have been staked on Illiance river outside this main size. It is located at the headwaters of the river in a country rock of tuff. The mineral deposit is a quartz vein containing silver-bearing grey copper. The vein strikes north and dips west. Two blocks of the vein offset by a cross-fault are exposed, and to trace the vein an obtain a better idea where it will be encountered at depth, surface work should be done.

A number of mineral claims have been staked in the area between the northeast fork at Kitsault and Illiance rivers, but this locality was not visited.

Properties on Lime and Roundy Creeks

The Cariboo is one of the groups of mineral claims in the region southeast of Alice Arm. The country rock is argillite and sandstone intruded by numerous sills and dykes of granitic material. The whole is extensively weathered. Molybdenite is present over a zone several hundred feet wide, but no commercial body has been exposed. Assays show white gold and silver values, and these metals are probably contained in pyrite, galena, and other minerals, disseminated through the rocks and quartz veins. It is interesting to note that immediately northeast of the property, lavas cover the older rocks. If the lava flows are of pre-Pleistocene age it is likely that products of Tertiary weathering such as secondary mineral deposits will not have been scoured off by Pleistocene glaciers in the area immediately surrounding the lava flows.

Nass-Skeena District

A different type of mineral deposit is found in this district. Some of the properties are of the silver-lead type, but the majority are gold deposits. Coal also is found in this part of the area. Only a few of the mineral claims were visited and none of those west of Tseax-Kitsumgallum valley was seen. The metallic mineral deposits here are chiefly narrow quartz veins where mining in a small way may be possible. There may be, also, large low-grade mineral deposits, but unfortunately, development has not proved the existence of any of this type. The future of coal mining in the district remains in doubt, and no workable tonnage has been proved. Drilling for oil will evidently not prove to be a successful venture.

Placer Gold—Douglas creek was worked in the early years of placer mining in British Columbia, and the creek still yields wages to a few men. The quantity of gold now taken out is not great, but gravel benches on the lower reaches of the creek and on the shores of Kitsumgallum lake near the mouth of the creek, might be tested to ascertain whether the gravels could be worked profitably on a large scale.

Coal. — Coal seams on the banks of Cedar river were described in 1914. The seams outcrop on the steep banks of the river, but are in many cases covered by small landslides. Some of the coaly material was obtained, but only from the weathered parts of the seams, and this material was chiefly graphite. Similar material was obtained from poorly exposed seams on Little Cedar river. If the material obtained can be used as evidence at all it tends to show that any coal found will be anthracite and will probably contain a good deal of graphite and schungite.

Petroleum. — One of the principal purposes of the writer's visit to the Kitsumgallum valley was to inquire into the possibility of finding petroleum in commercial quantities. No evidence was found to indicate the presence or former presence of petroleum in the valley. The sericite schists, Jurassic volcanic and sedimentary rocks, and the granitic rocks of the Coast Range batholith, need not be considered as probable containers of commercial petroleum. The shaly argillites of probable Cretaceous age remain. These rocks have been intruded by dykes and small stocks, and in some places art faulted and steeply folded. Marine fossils are scarce if they are present at all. No seepages and no residues from the former escape of oil were found. The absence of any evidence favouring the presence of petroleum, and the unfavourable geological evidence combine to discourage search for petroleum in the valley.

Kispiox valley. — A few days were spent in the Kispiox valley to investigate the probability of petroleum in commercial quantities. Although the time spent was brief it was sufficiently long to convince the writer that there is a dearth of any favourable indications.

No evidence was found to indicate that petroleum existed in the rocks. Until positive indications of the presence of petroleum are discovered, the idea of drilling for oil should not be entertained.

THE GOLD DEPOSITS AT MAKWA, ONTARIO

In September of last year T. L. Tanton examined a gold find one-half mile east of Makwa station on the Canadian National Railway, 77 miles northwest of Capreol, Ontario. A brief report is contained in *Summary Report*, 1922, *Part D.* of the Geological Survey. Between Makwa and Gogama, nine miles to the north there is a band of Keewatin schists about two miles wide, with granite on both sides. There is no definite boundary between the schists and the granite, and it is an "island" of this transitional rock that the gold occurs. There are numerous quartz veins, but these carry only low gold values. Spectacularly rich ore is found with limonite in joint planes in the rock. In places the joint planes and limonite are so abundant as to give the appearance of gossan. One sample of this material assayed $160 to the ton.

Dr. Tanton suggests that this gold has been derived by weathering from rock that formerly covered the present surface. The auriferous limonite is, then, the bottom three feet of a rich secondary deposit, the larger part of which was swept away in Glacial times.

In conclusion the report states "that the quartz veins are genetically related to the granite intrusion and that the rich secondary gold deposit has resulted from the weathering of a primary deposit during past geological ages. The surface examination indicates that no commercial deposit of gold ore has yet been encountered on the claims. It is possible, however, that further prospecting will reveal either larger bodies of secondary gold ore or richer primary deposits than are now known."

ALGOMA STEEL'S ANNUAL REPORT

The report of the Lake Superior Corporation recently issued contains the annual statement of the Algoma Steel Corporation, Limited, one of their susbsidiary companies, for the year ended June 30. In this company conditions were much the same as in the previous year. The rail mill was closed down from September 1 to February 19 and since resumption has operated at capacity. The 18" mill was closed down for more than half the year on account of lack of orders and for the greater part of the remainder of the time was on single turn. The 12" mill operated for about three months on single turn and for the remainder of the period was closed.

Net earnings of the Algoma Steel Corporation totalled $355,092 to which was added $112,500, dividends from subsidiary companies, making a total of $467,592. Disbursements on account of interest totalled $1,049,232, leaving a loss for the year of $581,639. Including a debit balance forward of $171,812 and United States income tax of $1,880 there is a balance at debit of $755,332. Current assets increased during the year from $6,990,872 to $8,254,241 and current liabilities from $1,930,675 to $3,818,749.

The Collieries of British Columbia

VI — Middleboro, Fleming, Princeton, and Chu Chua Collieries

By ROBERT DUNN

Middlesboro Collieries

The Middlesboro Collieries Ltd. is another enterprise being financed from Vancouver. It is capitalized at $1,107,700 and its officers are E. W. Hamber, president; G. S. Raphael, vice-president; Thomas Sanderson, managing director and secretary; C. M. O'Brian, treasurer, and Robert Fairfoul, mine manager. The mine and plant are one and a half miles west of Merritt. The mine is being worked on the coal measures of the northwest portion of the Nicola basin, on the west side of Coldwater River. Here the foothills rise to a height of about 700 feet and contain a number of good, workable seams of coal about six feet in thickness, having an average pitch of 30 degrees towards the south.

The No. 4 Mine is the largest and most important on this property. It consists of a horizontal tunnel driven from the foot of the hill on the same elevation as the tipple, following No. 5 seam of coal for a short distance. From this crosscut drifts are driven through the rock to Nos. 6 and 8 seams. Practically all the tunnelling on the main level is in sandstone rock a little below the footwall of the seams. Raises are driven to the seams, with the result that there is no trouble in maintaining good haulage roads when the pillars are extracted above this road.

Headings are driven from the main level following the full pitch of the seams to the surface croppings. where openings are made to facilitate the handling of timber and the ventilation of the mine. Dump-car roads or levels about 8 feet wide are driven from these headings, spaced 60 feet and following the strike of the seam. They are connected by crosscuts for ventilation purposes. Pillar drawing is commenced in the levels nearest the croppings and drawn back to the level on the retreating system, the headings being kept open as long as possible by cogs built on each side of the road.

The coal is loaded into small dump-cars at the various faces and trammed by hand to the headings, where it is dumped into the chute and conveyed to the main No. 4 level, loaded into the mine cars as required, collected by mule haulage and taken to the surface in trips by main and tail rope haulage.

No. 7 and No. 4 East Mines

No. 7 Mine is on the same seam of coal as No. 3 at the Fleming Colliery. The seam is about 16 feet thick and lies below the seams that are being operated from No. 4 mine. It was opened up from the croppings at the top of the hill by a pair of slopes following the full pitch of the seam and is mined by the pillar and stall method. The top 10 feet of the seam only is being extracted. Work in this mine at present, is confined to the drawing of pillars from the No. 4 levels to the croppings, so that the life of the mine is somewhat limited. The coal is hoisted by main rope haulage to the surface and lowered over a surface incline to the tipple.

No. 4 East Mine is a slope 1,200 feet to the east of the tripple, and is operating in No. 1 seam. The measures here are found to be subject to a great deal of faulting, causing mining to be restricted to the driving of the main heading and counter. All present work consists in the extraction of pillars in close proximity to the headings near No. 5 level. This is the only mine that is working to the dip below the level of the tipple. It shows the field to be subject to a great deal of faulting with depth. The mine cars are collected at the faces by horse haulage, are taken to a landing near the slope and from there hauled to the surface by main rope haulage.

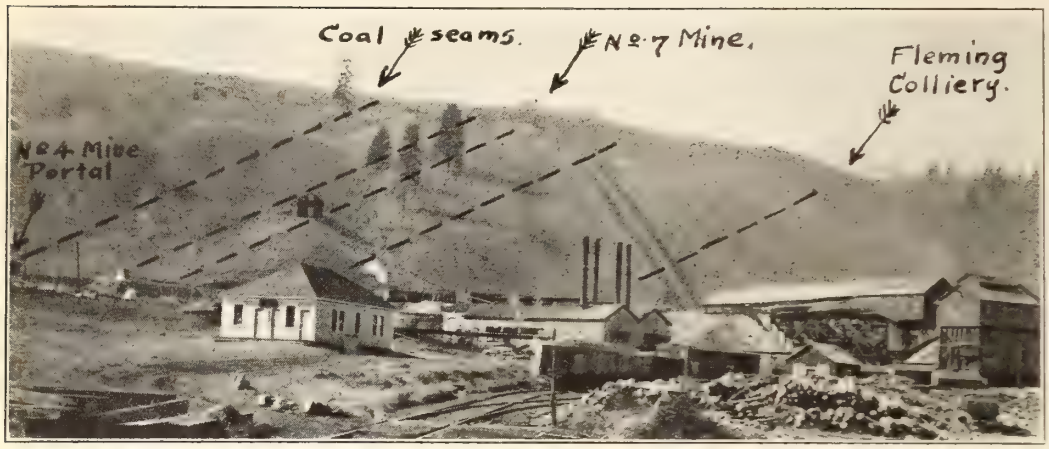
No. 4 East prospect is in a small area of coal near the outcrop of the 4 East mine. An entrance was made from the surface, connecting with the coal at a distance of 80 feet. The method of mining is pillar and stall.

As to plant and equipment, the coal is conveyed from the face to the mine-cars by chutes, and then hauled to the tipple by means of compressed air hoists and ropes. Ventilation is produced by a Sheldon fan 8.5 feet in diameter, direct connected to an Ideal steam engine, 14 by 18 inches, and is so arranged that the direction of the current can be changed. The main power plant is near the tipple, consisting of four return-tubular boilers, each 160 H.P.; Canadian cross-compound compressor with a capacity of 2,000 cubic feet of free air a minute; Ideal compound engine direct-connected to 75 K.W. 2,300-volt General Electric generator; and a 25 K. W. direct-current steam-engine set for lighting purposes.

Fleming Colliery

Another colliery that has been directed from Vancouver is the Fleming Coal Co. Ltd., at the head of which for years was Mr. Joseph Martin, who died some months ago and whose name will long be remembered as one of those prominently associated with the early political history of Canada. Mr. Martin had the utmost confidence in the potentialities of the coal industry of the Nicola district. The Company's operations of late have been in the southwest portion of the Nicola field, the mine being about 1½ miles from Merritt. Other officers are Joseph Graham, managing director and A. E. Smith, manager.

Work ceased last February owing to exhaustion of No. 2 Mine. This was on a seam of an average thickness of 6 feet which was developed by the pillar and stall method under favorable conditions. Owing to the pitch of the seam, the coal was conveyed from the various faces by means of chutes to the main levels where it was loaded into mine cars. Considerable prospecting has been done with a view to the opening up of the measures on other parts of the property. A nine-foot seam was uncovered but, as it was not conveniently located, a rock tunnel was driven at the foot of a hill and, when driven some 500 feet, a six-foot seam was cut and was developed to some extent by levels in the seam. The tunnel was continued about 70 feet and a bore-hole was run into the roof, proving a seam of coal about 25 feet above. As stated above, however, all operations have come to



Middlesboro Colliery, showing the location, of coal seams in the hillside, the incline from No. 7 Mine, the tripple and the power plant.

an end for present, no doubt owing to the unsatisfactory condition of the market.

The plant consists of two Leonard-return-tubular boilers with a joint capacity of 80 horse-power, which provide power for the main haulage, fan-engine and lighting plant, and heat for the wash and change house; a 25-horse-power vertical boiler near the tipple, which provides power for a small hoist and for a pump to elevate water from a storage-tank at the tipple to a tank at the mine; while a small pumping plant is situated at the river, delivering water to the storage-tank at the tipple.

The surface equipment consists of machine, carpenter, and car-repairing shops, office buildings, and wash and change rooms at the mine.

Princeton Coal & Land Co.

The Princeton Coal & Land Company Ltd. which is on the bank of the Similkameen River near the town of Princeton, is capitalized at $1,000,000 and its directors include A. St. George Hamersley, Chairman, and E. S. Neave, secretary, of London, England. Ernest Waterman is the general manager and Francis Glover the manager, both the latter being resident at Princeton. The measures are reached by two 12 per cent. slopes driven on the dip of the seam, which, where cut 200 feet from the portal of the main slope has an average thickness of 20 feet. It is being exploited by the pillar and stall system, work being restricted usually to the upper ten feet of the seam. Of late the coal has been taken from the pillars and a small section lying to the west of the slopes. The workable area is small and of late operations here have been confined to the drawing of pillars in close proximity to the main slope. Little blasting is required. Ventilation is provided for by a single inlet, belt-driven fan of the Guibal type, placed near the entrance to the counter slope.

New Entry in Good Coal Seam

The management of the Princeton Coal and Land Co., have been successful in driving a 12 per cent. 8 x 10 haulage slope from the surface through 120 feet of sand and gravel. This connected the new prospect on the east side of the old No. 2 mine, where a 7-feet seam of coal overlaid by hard sandstone has been proved. Workmen are at present engaged in erecting the necessary equipment, track and sidings for connecting this new entry with the No. 1 Mine tipple, which is 1,500 feet southeast of the new opening. This will open up and develop a large area of virgin coal land, where the structure and quality of the coal is expected to show a marked improvement.

The coal produced in this colliery may be considered as a high-grade lignite and when cleaned it is considered a good domestic fuel. A large portion of the production finds a ready market in the coast cities. Practically all the coal produced is machine mined, very little blasting being required, the object being to produce as large a proportion of lump as possible. The surface equipment consists of a wooden tipple provided with a rotary dump, by which the mine-cars are emptied upon a stationary 2-inch bar-screen, from which the large coal is cleaned and loaded into the railway-cars, the small coal falling upon a small hanging shaking screen of ¾ inch mesh, whence the large portion of the screenings is collected by a belt-conveyor, dumping into a chute.

The power plant consists of three return-tubular boilers with an aggregate capacity of 200 H.P., supplying power for a Canadian Rand air-compressor with a capacity of 750 cubic feet of free air a minute, used for running the hoists, mining machines, and pumps in the mine. A 25 horse-power steam hoist near the tipple is used for hoisting the mine-cars from No. 1 mine.

A well equipped machine-shop, car repairing and carpenter's shop, with wash and change room and lamp-room, are maintained, while a 30,000-gallon water-tank provides for the storage of water for use at the plant and also for fire-protection purposes.

Chu Chua Coal Co.

American capital, mainly from the State of Washington, is behind the enterprise at Chu Chua known as the Chu Chua Coal Co. Ltd. The directors are A. H. B. Jordan, president; W. H. Glass, vice-president; Q. A. Thomas, general manager, Major H. S. Hodgson, secretary-treasurer; and David Brown, manager. All, with the exception of the manager, have their headquarters either at Everett or Seattle, Wn. The property, the development of which was commenced only recently, is 55 miles north of Kamloops on the north side of the Thompson river and comprises part of the foothills and flats on each side of Coal Creek.

There are several outcrops of coal, the chief of which are the "Thomas," "Smith" and "Gray" seams. Until the year 1921 all the development work had been done on the upper Thomas seam. This is about 3 feet in thickness, including bands of rock

The coal is of a good quality and commands a ready market in Kamloops.

This coal seam is being developed by the longwall system. As it is overlaid with a sandstone roof dipping into the hill at an angle of 12 degrees, mining conditions are favourable. With depth the seam was found to become thinner, while the rock bands were more pronounced and, as a result, operations were closed at this mine during February of the present year.

During 1921 the "Gray", or lowest seam to be seen on this property, was uncovered by removing the glacial drift in the Creek. A thirty-degree slope was commenced at the surface at the foot of the hill and encountered the seam at a distance of 80 feet, when it was opened up by the pillar and stall method. This seam was found to be of poor quality and as a result work was discontinued.

All development work thus far has been on an upper series of the measures where the coal is found exposed at the side of the creek. Below the "Gray" seam the surface flattens considerably and the measures have a heavy covering of glacial drift and river silt.

John Hutchinson, mining engineer of Everett, Washington, inspected the property last January and strongly advocated that the company drill below the "Gray" seam.

Portable Electric Drills In Mines

By W. E. BALLARD*

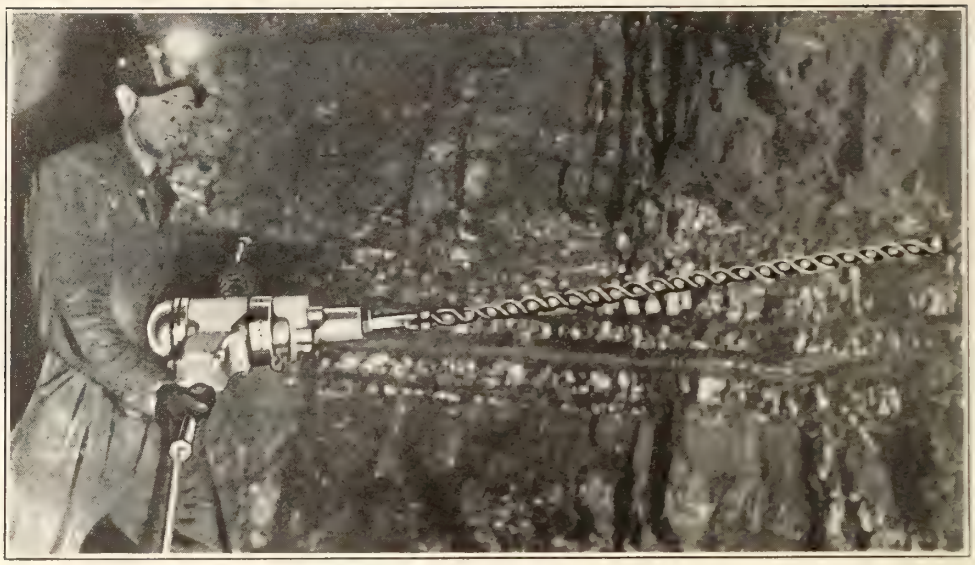
Ever since the mining of coal on his continent assumed the proportions of an industry, it has been almost the universal practice to permit the miner to bore his own shot holes. It may be said with equal truth that the same practice is followed in charging and firing shot holes. To the layman the handling of explosive appears to be a somewhat dangerous proceeding, and he is surprised that there has been so little change in general practice since the commencement of the industry. He is forced to admit that, although we pride ourselves on the rapid strides we have made in the past few decades in transportation, communication, manufacturing and many other lines of industry, after all in a great many lines of endeavor we are but the slaves of tradition and simply continue to do things as our ancestors did.

However, there are some coal mining companies that have recognized the possibility of increasing their production by boring the shot holes for the miners by power; and they have likewise reduced the danger of mining by having the holes charged and fired by a man who has been specially trained in this work.

Electricity is the preferred power for use in drilling shot holes, as it is usually present in the mines already for the use of modern machinery, such as cutters, locomotives, loaders and pumps. When the coal mine operator first thought of using power instead of manual labor to bore holes he naturally looked for a machine to bore his harder materials, and this lead to the devel

* Mining Specialist, Black & Decker Co., Baltimore, Md.

Portable Electric Drill mounted on a light column to drill coal of soft rock



Portable Electric Drill in a Coal Mine

opment of an admirable tool for the work. It has sufficient weight to enable it to hold the cutting auger or drill up against the material to be cut, and is mounted on wheels that fit the mine tracks and permit it to be moved around from place to place by the mine locomotives.

A little later the progressive operator wanted a lighter tool to bore his softer materials, and this led to the application of the light portable electric drill to the job. Such a tool weighs from 25 to 35 pounds. This tool bores shot holes in soft coal in a surprisingly short time, and can be operated by one man, as well as carried from place to place, together with the necessary augers. The builders of portable electric drills have been enabled to keep the weight down, without sacrificing power or strength, by the use of a special aluminum alloy in the manufacture of the field and gear cases and commutator cover.

The next step was to use a more powerful drill in the harder coal. For such work a tool has been developed which, although it is fitted with a motor conservatively rated at 1¼ horsepower and has a gear reduction of 35:1 between the motor shaft and the auger spindle, has a weight of but 55 pounds. This is a two-man tool, not because of its weight, but because of the power it develops. The writer has seen this drill used as a one-man tool but considers such practice undesirable, as the torque developed when the auger hits a hard substance such as a sulphur pocket is more than one man can resist, and he is apt to be injured before he releases the automatic switch that cuts off the power.

In working comparatively thin seams of coal, it is advantageous to use the lighter tools in boring shot holes in slate or sandstone when it is necessary to take down the roof or take up some of the floor. For such work the two men operating the drill have not the physical strength to force the cutting edge into the material, and it becomes necessary to use a hand-operated post drilling machine fitted with a feed bar. The electric drill, of course, is substituted for the hand power. Such a combination is inexpensive and is light enough to be moved around by two men. In many instances the restriction imposed by lack of space make it impossible to use a long feed bar, and although it is necessary to use three augers, two, four and six feet in length, in drilling a six-foot hole 1¾ inches in diameter, two men can easily drill two such holes in a place in 20 minutes. The actual boring is done at a rate of about two feet per minute.

While a great many operators continue to use 1¾-inch augers in boring their shot holes, some have recognized the advantage of boring a hole 1 inch in diameter. The smaller hole requires approximately one-half the energy required to drive the larger hole the same distance.

There is no doubt that in a few years, as the knowledge of the more modern methods of mining spreads among the coal mine operators, the boring of shot holes by the miner will become a thing of the past. With the passing of that practice will also come the charging and firing of shot holes by the "company", and one more hazard of the mine will be removed.

BRICKS FROM MINE DUMPS

It is believed that at last the mine dumps of the Rand will be turned to commercial use by the manufacture of bricks. It appears that some time ago Mr. W. Ingham, chief engineer to the Rand Water Board, caused to be sent oversea, for testing in the new plant that has produced lime-sand brick for actual buildings, hermetically sealed samples of sand from the dumps of the George Goch, Ferreira and Robinson Deep Mines, together with quantities of white and blue lime from the Nothern Lime Co. and the Ventersdorp Co. The sands were first freed from all trace of cyanide. Mr. W. Arnott, engineer, of Glasgow, took these samples of sand and lime to the Continent and there personally inspected the process. As a result, samples of bricks have reached Johannesburg, and it is claimed that they fill all the purposes of faced bricks at a low cost. They are hard, and grey-white in colour. They have been inspected with great interest, and a company has been formed. It is stated that 56,000 of these bricks can be turned out per day at a cost of 27s. 6d. per thousand. In his report Mr. Arnott says the bricks "are better than the best clay bricks, and are justly known as hard bricks. A crushing resistance of over 4,000 lbs. per square inch has been obtained, and a degree of hardness far surpassing clinker bricks." — "South African Engineering and Mining Journal."

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

Interim Report by Mining Corporation.—The Mining Corporation has issued an interim report on its properties in South Lorrain. The report states the company now holds approximately 500 acres, of which only a comparatively small proportion has been developed. The undeveloped portion has the same favorable geological features as the part which has already given such a substantial production, and it is estimated that several years will be required to explore this northern part. To date the ounces of high grade ore produced by hand picking amounts to about 1,500,000. In addition to this 120 tons of low silver, high cobalt ore has been produced and marketed for its cobalt content. There is also available on the dump 8,000 tons of mill ore, estimated to contain 250,000 ounces. This large production has come from development work and from limited stoping operations, the greatest production being from a stope 100 feet long, 80 feet high and 6 feet wide. A number of promising showings on veins which produced silver have not yet been developed. Development and exploration work has been retarded by the limited shaft capacity. A new shaft, however, has been sunk to a depth of 550 feet and will be in operation in October, when underground work will be out on a much more extensive scale. The report gives details as to the work done and contemplated on different veins and states that exploration work has just reached the point where past experience justifies the hope of very important developments. The holdings of the company have, as yet, been merely scratched, and it will take years of work to explore the properties' possibilities.

To Enlarge Schumacher Shaft.—The Hollinger proposes to enlarge its Schumacher shaft so that it will be 15 feet square in the clear. Work of enlargement will be carried on simultaneously from the surface and from the 800 foot level, and when completed it will be continued to greater depth. The company is installing a large amount of new machinery for both the mill and the mine. The crushing plant now has a capacity of 8,000 tons a day and three new rod mills of 800 tons a day capacity each are being installed and replacing stamps. New tanks are being erected and the capacity of the mill will gradually be enlarged. Although all these plans are being carried out with a view to treating 8,000 tons a day, the management states that it does not contemplate any immediate increase above the tonnage of 4,500 tons a day now being treated, giving as an excuse that this will not be done until there is a continuous supply of ample power to permit of operating at this capacity steadily. The management intimates that another power shortage is expected this winter, but the power officials state that they do not expect one and that they are in a position to contract for approximately 5,000 additional h. p.

Dome's August Production.—During the month of August the production from the Dome amounted to $431,019. This compares with $435,547 in July and with $352,774 in August 1922.

Mill on Nighthawk Peninsula.—Good progress is being made with the construction of the 200 ton mill on the Nighthawk Peninsula. Most of the machinery is on the ground and some of it has been erected. Tanks are now being built and the mill building is now completed. If the present rate of progress is maintained, it is expected that the mill will be in operation some time in November.

MacEnaney Mine Closes Down.—The MacEnaney Mine, formerly known as the Hollinger Reserve, has been closed down. It is understood, however, that the company anticipate doing further exploration work by means of diamond drilling. In the same vicinity the Hayden shaft has reached a depth of 720 feet, and sinking will be continued to the 1,000 foot level. Work has been stopped on the Moneta property, adjoining the Hollinger, on which operations have been financed by the Kirkland Lake Proprietary. It is understood, however, that the Proprietary has not taken up the second block of treasury shares, and presumably does not propose to continue further exploration work.

Vipond Annual Meeting.—The annual meeting of the Vipond has been called for September 20th. The notice calling the meeting is accompanied by a financial statement showing that there is approximately $215,000 in the treasury. Underground developments continue to be favorable and the mill should be started this fall.

Kirkland Lake.—The Bidgood Mines in Kirkland Lake, on which approximately $300,000 has been spent to date, is in need of further funds, and in order to provide the necessary money a Toronto syndicate, headed by Homer L. Gibson, has agreed to take an option on the unissued treasury stock, provided all the stock holders will pool their stock for a period of nine months, subject to an option by the syndicate to purchase one half of the shareholders' stock at a price of 25 cents a share. The President has written a letter to the shareholders stating that he believes the proposition to be a fair one and advising them to deposit their shares with the Trust company. Development to date has been confined almost entirely to No. 9 vein, on which commercial ore shoots have been found on the 300 and 400 foot levels, but the ore has not been in sufficient quantities to justify preparations for milling.

It is stated that an amalgamation of the Tough Oakes and Burnside, with three other claims in the Kirkland area, will shortly be announced. Development work is being carried on at the 800 foot level of the Tough Oakes, and satisfactory results have been met with.

Blue Diamond Coal Mine.—For the year ending June 30th, 1923, the annual report of the Blue Diamond Coal Mine, which is owned jointly by the McIntyre and Temiskaming Mines, shows operating profits of $157,343, a decrease of $9,000 compared with the previous year. After deducting interest amounting to $48,135 and Taxes, Royalties and Rentals of $68,486 there remained a net profit of $40,732, a decrease of $15,000 as compared with 1922. The balance sheet

shows advances of $580,000 from the holding company and a surplus of $65,753.

Larder Lake.—On the 550 foot level of the Crown Reserve property in Larder Lake, 270 feet of drifting has been done on the No. 1 vein, which shows a width of from 14 to 41 feet. 200 feet of drifting has been done on No. 2 vein, and assay results on both of these ore bodies are stated to be satisfactory.

Syndicate Negotiating.—It is reported that a syndicate is negotiating for 1,000,000 shares of Baldwin stock in order to provide sufficient money to carry on further development work. The Barrey-Hollinger, which is the old Patricia Mine, will sink from the 200 to the 500 foot level, and will open levels at 350 and 500 feet. The vein is about 8 inches wide and carried good values in places.

Option Dropped.—The Tonopah Mining Company has dropped its option on the Moffat Hall property, and John Taylor & Sons of London, have dropped their option on the Kitchener Kirkland.

NOVA SCOTIA

New Waterford District—Preparations for sinking another large shaft in the New Waterford District have begun. A railway spur is being laid from the main line into the location of this colliery, and when it is completed material will be taken in by rail and the work of sinking will then begin. Like all other shafts lately put down, it will be sunk as close to the coast line as safety and practice will permit. The shaft will tap the Phalen Seam, and the most of the workings will be under the sea. The coal is known to be of good quality, as the upper part of the workings of the old Lingan Colliery, which is in close proximity was about eight feet thick. This colliery was worked for a number of years, and closed down about forty years ago. The shaft will not be very deep at the point of location, and as the strata is well known the cost of sinking should not be very large. However, nearly every colliery put down at the present time, requires a very large expenditure before the surface equipment is complete, and the mine ready for a large output.

The site for a colliery village is an ideal one, the exposure being towards the south, the land lying along the Lingan Harbour, and quite close to the old shipping piers. Without doubt, it will make one of the most beautiful colliery villages in the Island, as there is a gradual slope towards the shore, which will favor drainage, when the houses are built. The location is also central and lies between the collieries in the Glace Bay District and that of Waterford. Nothing but shaft sinking may be done this winter, but even that is going a long way in preparing for a new mine.

Much Idle Time—The collieries are having considerable idle time, due to the want of shipping and there is a feeling that strike conditions during the summer has had to do with this matter. At that time it was given out that large orders held by the coal Company were cancelled, and coal was sought for elsewhere. It now looks as if there was considerable truth in this statement, and men are beginning to fear that an inactive winter is before them. It is too early yet to state what winter conditions will be, but from what we know now, it is likely that there will be considerable work.

Some Mines at Wabana Close Down—Some of the ore mines of Wabana have closed down and quite a number of the men are out of employment. As long as it was possible the mines were kept in operation. Much work was done last winter, however, which could have been left off until the summer, but was undertaken because it would give employment to many men. Had there been prosperity in the iron trade, the mines would have operated until the end of the season, but as it is there are sufficient of them left operating to more than supply the demand.

Rescue Breathing Apparatus Corps—Miners of the Stellarton and Westville District had a very good illustration of the work of the Rescue Breathing Apparatus Corps of the Acadia Collieries on Labor Day. These corps are said to be the more efficient and best equipped in the Province of Nova Scotia and have done excellent work in times of mine fires and other mine troubles. Indeed the Stellarton Corps was on one occasion asked to go up to Halifax, and help them put a fire out, which had occurred in one of the vessels. Although the fire had been raging for a considerable time, they were successful in putting it out.

A number of new corps are being formed at the Cape Breton collieries, and will be equipped with the latest and best type of Self-Contained Breathing Apparatus. The Dominion Coal Company have taken a long time to select the type most suitable to the district, but have reached the stage when the choice lies between two. A meeting will be held next week to decide which of the two will be selected. As stated before in the "Canadian Mining Journal" it is the intention to give as much public information as possible upon the result of the test of the four different machines—the Proto, Meeca, the Gibbs, and Paul

BRITISH COLUMBIA

Rossland—With regard to the reports of the discovery and shipment of ore from the I. X. L. and Golden Drip Mines, near Rossland, carrying values so high that the railways refused to accept the risk of its transport to the Trail Smelter it is interesting to note that A. G. Langley, resident mining engineer at Revelstoke, B.C., who was quoted by newspapers as having stated that in visiting the I. X. L. he saw gold "standing out in chunks", denies making the statement and declares that he has not visited the Rossland District of the Province this Summer.

It would appear that, at least in point of Mr. Langley's comments, the reports have been exaggerated. This, however, does not discredit the properties in question. There is no doubt that rich ore has been found and Mr. Langley simply says that he has not had the opportunity this Season of confirming it in person. He went over the I. X. L. last year and refers those interested in his observations to his report published in the Annual Report of the Minister of Mines for last year.

In view of the interest recently created it is pertinent to quote Mr. Langley. He says:

The I. X. L. is "situated within 2½ miles of Rossland on the Northport road and has been worked under lease by R. B. Shelledy, J. J. Hawkins, and associates. It belongs to John S. Baker, of Tacoma. Very rich gold ore has been extracted from the upper

part of the vein since recent work was started in 1921. The ore has been shipped to the Bunker Hill and Sullivan smelter at Kellogg, Idaho. The vein is a small quartz filled fissure in serpentine. It strikes in an easterly and westerly direction and dips at about 40 degrees. The vein is exposed along the drift for about fifty feet but with the exception of a small shoot of ore is barren. The ore occurs where the vein has been faulted, which action has caused a displacement of about 3 feet. The gold bearing quartz has been fractured, which gives it a slightly banded structure. Native gold occurring as flakes along seams in the quartz is plainly visible to the naked eye. Associated minerals are siderite, iron and copper sulphides. The last shipment of about 3 tons of sorted ore is said to have yielded nearly 300 oz. in gold to the ton. The shoot from which this was mined is about 16 feet in length and about 8 inches wide. Sinking was being continued on this ore and further exploratory work was under consideration at the time of examination in June."

Cedar Creek—The original stakers on Cedar Creek, Cariboo District, British Columbia, made application recently for permission to commence action in the Supreme Court of the Province to regain possession of the claims they located and which were sold to the Cedar Creek Mining Company for $180,000 of which amount $123,000 was paid. The Company now has other difficulties and the Court refused the application giving as his reasons that a substantial proportion of the sale price had been paid, that there was a difference of opinion between litigants as to the amount due, and that the Company had not title to the property pending the decision of a number of mechanic lien actions pending against it.

Wind Pass Mine—Late reports having reference to the Wind Pass Mine, near Chu Chua, B.C., are favourable. This is another property in which W. R. Wilson, president of the Crow's Nest Pass Coal Co. and a large holder of Premier Gold Mining Co. stock, is interested. Development work is being pushed with energy, in a new and lower tunnel a substantial body of good ore has been struck and, as soon as this is proved further, it is certain that active steps will be taken to put the mine on a producing basis. The installation of the plant necessary to make the mine as self contained as possible in point of the treatment of the mineral is being considered. The importance of this to the district tributary to Kamloops, B.C., is evident and it appears that the optimism of the resident engineer for the district, Major A. W. Davis, with regard to the mining possibilities of this part of the central section of the Province, is likely to have early practical justification. In a recent statement Major Davis, while speaking of the Wind Pass in favorable terms, deprecated the tendency to exaggerate present proven prospects in the Whitewater District, which lies in the mountainous region back of the town of Lillooet. He thinks some of the press reports would stand toning down although the country is a good one for prospectors and what may develop into important discoveries have been made. This area, he points out, is adjacent to the coast batholith where everywhere in this province important producing areas have been developed. It is his intention to visit the Whitewater country again this season before the snow flies.

Slocan Mining District.—In the Slocan Mining District of British Columbia there is general activity, many properties being worked on a small scale by leasers. The R. E. Lee, a property worked for several years, has produced 14 tons which is ready for shipment; the Washington Mine, which has been under constant development for months, recently shipped 40 tons, and the Ruth Mine, which has been bonded to Vancouver interests, is looking good enough to draw favourable comment from R. H. Stewart, mining engineer, who has been inspecting a number of prospects in that locality. Regular shipments are being made from the Wonderful Mine to the Clarence Cunningham Mill at Alamo and Mr. Cunningham also has started work on the Van Roi Mine at Silverton. Leasers are said to have found ore in the Rambler-Cariboo and the Queen Bess. The Silversmith is working three shifts in mine and mill with gratifying results to shareholders.

Greenwood.—The excitement caused by late developments on the Combination Mine, Eholt Mining Co., near Greenwood, B.C., is warranted if current reports are authentic. It is said that the new ore recently struck runs $250 to the ton. Assay returns reported from samples taken by P. B. Freeland, government mining engineer, are 2.6 ounces gold and 303 ounces silver to the ton together with 13 per cent. lead and 12 per cent zinc. The high grade is 9 to 12 inches wide and lies in a vein 2 feet wide. It was struck by crosscut at a depth of 175 feet vertically and at a point 222 feet from the portal of the tunnel. The ore has been followed by a drift for from 10 to 12 feet. The Combination adjoins the Providence from which ore to the value of about one and a half million dollars has been shipped and the stockholders for the most part are residents of the City of Spokane.

Maple Leaf Mines Assignment.—The Maple Leaf Mines Ltd. has assigned under the Bankruptcy Act to Denis St. Denis, of Nelson, authorized trustee. This action prevented the mine, situated in the Franklin Camp, near Grand Forks, being sold by the sheriff to satisfy a judgment creditor, H. W. Young, former managing director.

The Jubilee Mining Co., has been incorporated to take over and develop the "Spotted Horse" a Crown granted group of mineral claims situated on Jubilee Peak overlooking the town of Greenwood. Surface stripping and other work has started, the necessary plant is to be obtained, and the new company looks forward to making shipments shortly. Assays of ore taken from the exposed ledge are given as $8 gold, 104 ounces silver, and a considerable percentage of lead to the ton.

Field Meet at Ladysmith.—A Mine Rescue and First Aid Field Meet was held at Ladysmith, B.C., on Labor Day, September 3rd, under the auspices of the Vancouver Island Mine Safety Association. Teams were in attendance from the most important of the coal mining centres of the Province including Cumberland, Ladysmith, Nanaimo, Cassidy, South Wellington and Fernie. Each outside community sent a large coterie of supporters and the contests were closely and enthusiastically watched. Hon. Wm. Sloean, Minister of Mines, George Wilkinson, Chief Inspector of Mines, and Thos. Graham, who has been appointed to the position of General Manager of the Canadian Collieries (D) Ltd., in place of J. M. Savage, deceased, were present. It may be said here, as an aside, that the news of Mr. Graham's appointment has created a very

favorable impression in coal mining centres on the Island and among business men throughout the Province. The same may be said of the announcement of the elevation of Charles Graham, a brother, to the post of General Superintendent, formerly held by Thos. Graham. After the sports the prizes were presented by the Hon. Mr. Sloan.

The results of the competitions follow:

Mine Rescue Event: 1st, Capt. T. Williams' team, Cumberland, 93.2; 2nd, Capt. Coufield's team, Fernie, 93; 9rd, Capt. Broderick's team, Nanaimo, 89.4.

First Aid—B. C. Mines Cup: 1st, Capt. J. Barton's team, Nanaimo; 2nd, Capt. Beveridge's team, Cumberland.

Coulson Cup: 1st, Capt. Beveridge's team, Cumberland; 2nd, Capt. J. Delaney's team, Ladysmith.

One Man Event: 1st, J. Thompson, Nanaimo; 2nd, Mr. Hewlitt, Ladysmith.

Two Man Event: 1st, J. B. Stewart (Capt.), Cassidy; 2nd, W. Thorpe (Capt.), Nanaimo.

Jvenile Event: 1st, C. Wharton's team, Nanaimo; 2nd, Mr. Wilson's team, Ladysmith.

Ladies' Cup: 1st, Mrs. Hudson (Capt.) Cumberland; 2nd, Mrs. Delaney (Capt.), Ladysmith; 3rd, Mrs. Rutherford (Capt.), Nanaimo.

The annual mine rescue and first aid competitions of the East Kootenay Mine Safety Association were held at Michel, B.C., on Saturday the 1st September. There was an entry of seven mine rescue and ten first aid teams, two of the former and three of the latter coming from the coal fields of the Province of Alberta and the remainder representing eastern British Columbia. W. R. Wilson, president of the Crow's Nest Pass Coal Co., presented the prizes.

Following are the results:

Mine Rescue: 1st, Coal Creek, Capt. J. Caulfield; 2nd, Michel No. 2, Capt. M. Littler; 3rd, Fernie No. 1, Capt. E. Hesketh; 4th, Michel No. 1, Capt. A. Howden; 5th, Fernie No. 2, Capt. W. Hynds; 6th, Bellevue, Capt. J. J. McIntyre; 7th, Lethbridge, Capt. W. S. Crawford.

Senior First Aid: 1st, Fernie, Capt. J. Hamer; 2nd, Michel No. 1, Capt. W. Fowler; 3rd, Bellevue, Capt. J. Milnes, and Lethbridge, Capt. W. W. Short, tie; 5th, Michel No. 2, Capt. D. Izatt; 6th Coal Creek, Capt. J. Eccleston.

Ladies' First Aid: 1st, Coal Creek, Mrs Miller (Capt.); 2nd, Michel, Mrs. Mossby (Capt.).

Junior First Aid: 1st, Fernie Boys' Scouts, Capt. J. Larmont; 2nd, Hillcrest, Capt. C. Smith.

Coal Mining.—Coal mining in British Columbia has been proceeding, more or less uneventfully, during the last few weeks. On Vancouver Island conditions are about normal, both as to production and in respect of the state of mind of employer and employee. A misunderstanding as to contract rates closed down the Wakesiah Mine, Western Fuel Corporation of Canada, Nanaimo, for one day, a speedy adjustment sending the men back to their work the day following the walk-out. The appointment of Thos. Graham to the position of General Manager of the Canadian Collieries (D) Ltd. is accepted as meaning that the Company, for the present at least, is satisfied to continue the policy of the late J. M. Savage of combining exploitation of the Company's extensive island coal bearing areas to the point of present market requirements with constant exploration and development. Under the direction of Mr. Graham and his brother, Charles Graham, it is felt that the administrative and the operating branches of this important enterprise will be competently handled.

In the Nicola-Princeton Field the cessation of operations on the part of the Fleming Coal Co., following the death of the late Joseph Martin, one of its chief owners, has had its effect on the production. That, however, has been off-set to some extent by increases in the output of the Coalmont Coal Co. In this connection the recent announcement of the English Syndicate which has secured control of the Princeton Coal & Land Co., that these holdings are to be more energetically exploited and that the monthly production may be expected to jump from about 125 to 500 tons a month is encouraging.

It would not be surprising to find the Coal Creek Collieries curtailing their production as a result of the conversion of most of the Great Northern Ry. locomotives to oil burners. This, however, has not yet been apparent. Evidently the collieries of the Crow's Nest Pass have been able to find alternative markets up to the present. The Trail Smelter, Consolidated Mining & Smelting Co., of Canada, now is taking considerable quantities, a reserve supply of fuel having been almost exhausted. It is known, too that the enterprise of eastern British Columbia Collieries has been rewarded with some first class contracts on the prairies. It is possible, therefore, that the output of the mines may be maintained at the normal rate of previous years notwithstanding the serious blow that has been dealt an hitherto steady export market.

Several accidents have occurred recently in the mines of the Western Fuel Corporation of Canada, Nanaimo, B.C. J. Blades and R. Morgan, coal miners, were killed in a fall of rock which extended a distance of thirty feet back from the face. They were engaged on pillar work in a place twenty feet high when the cave took place. A fall of rock in the Wakesiah Mine of the same Corporation injured Wilson McLellan, a coal miner, who is on the way to recovery.

ALBERTA

Much Unemployment.—Reports from the western coal fields of the Province of Alberta indicate that there has been considerable unemployment during the summer. A reduction in the demands of railroads and the weakness of the domestic market are given as the reasons for this condition. It is said that 3,000 miners have been out of work in the Alberta section of District 18, U. M. W. of A. and that in other fields the mines have been running half time. The trade has been markedly slack on the Drumheller Valley, the towns of Drumheller, Wayne and Rosedale being most affected.

The relations between the operators and the miners in Alberta have been better than was anticipated. A strike was promised in the Edmonton-Clover Bar Field, chiefly because of the declaration of independence of the U. M. W. of A. by seven mines in the district. Pickets maintained at the mines since December 1st, 1922, according to report, have been withdrawn and in addressing a strike meeting at Beverly, Alberta, W. A. Shermon, president of District 18, U. M. W. of A., is quoted as admitting failure to break in on the local union.

Advertisements other than "Employment Wanted" or "Employees Wanted" will be inserted in this department at the rate of 20 cents per agate line (14 agate lines make one inch). $2.80 per inch, each insertion, payable in advance. Space measured from rule to rule. When four or more consecutive insertions of the same advertisement are ordered a discount of 25 per cent. will be allowed.

Advertisements of "Wanted Employment" or "Wanted Employees" will be inserted at the rate of two cents a word, net. Cash must accompany order. If box number is used, enclose ten cents extra for postage in forwarding replies. Minimum charge 50 cents.

SITUATION VACANT Person to act in the capacity of publications assistant. Must be competent to edit MS. and correct proofs of geological and mineralogical matter, and thoroughly conversant with all details connected with putting publications into print. Apply Box 613 Canadian Mining Journal, Gardenvale, Que.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows Placer Gold, $76,542,203; Lode Gold, $109,647,661; Silver, $59,814,266; Lead, $51,810,891; Copper, $170,723,242; Zinc, $24,625,839; Coal and Coke, $238,289,565; Building Stone, Brick Cement, etc., $36,605,942; Miscellaneous Minerals, $1,358,839; Making its mineral production to the end of 1922 show an

Aggregate Value of $734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive $94,547,241; for five years, 1896-1900, $57,605,967; for five years, 1901-1905, $96,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for 5 years 1915-1920, $189,922,725; 1921, $28,066,641; for the year 1922, $35,158,843.

Production During last ten years, $339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing

VICTORIA, British Columbia
THE HON. THE MINISTER OF MINES.

PROVINCE OF QUEBEC

MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

MINER'S CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONORABLE J. E. PERRAULT,

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

Jones & Glassco, Regd.

Copper:—
Consolidated Mining & Smelting Co.

Countershaft Fixtures:
Dodge Manufacturing Co.

Couplings:
Dodge Manufacturing Co.
Hans Renold of Can., Ltd.

Cranes:
Link-Belt Limited.
Canadian Mead-Morrison Co.
Peacock Brothers, Limited.

Crane Ropes:
Allan Whyte & Co.
Canada Wire & Cable Co.
Greening B., Wire Co., Ltd.

Crucibles:
The Mine & Smelter Supply Co.

Crusher Balls:
Canada Foundries & Forgings, Ltd.
Herbert, Alfred, Limited.
Holman, Bros., Ltd.
Hull Iron & Steel Foundries, Ltd.
Peacock Brothers, Limited.
The William Kennedy & Sons, Ltd.

Crusher Jaws:
Canadian Steel Foundries, Ltd.
The William Kennedy & Sons, Ltd.

Crushing Rolls:
Canadian Steel Foundries, Ltd.
The William Kennedy & Sons, Ltd.

Crushers — Jaw & Gyratory:
Canadian Ingersoll-Rand Co., Ltd.
Herbert, Alfred, Limited.
Holman Bros., Ltd.
Hull Iron & Steel Foundries, Ltd.
Lymans, Limited.
The Mine & Smelter Supply Co.
Hadfields, Limited.

Cut Gears:
Hans Renold of Can., Ltd.
Jones & Glassco, Regd.
The William Kennedy & Sons, Ltd.

Cyanide:

Cyanide Plant Equipment:
The Dorr Co.
The Mine & Smelter Supply Co.

Diamond Drill Contractors:
Smith & Travers
Sullivan Machinery Co.

Diesel Engines:
Belliss & Morcom, Ltd.
Laurie & Lamb.
Lammers & Maase, Ltd.

Dies:
Canada Foundries & Forgings, Ltd.
Herbert, Alfred, Limited.
Hull Iron & Steel Foundries, Ltd.
Holman Bros., Ltd.

Dredging Ropes:
Allan Whyte & Co.
Greening, B. Wire Co., Ltd.

Dredges:
Canadian Mead-Morrison Co.

Dredger Pins:
Hull Iron & Steel Foundries, Ltd.

Dredging Machinery:
Hadfields, Limited.
Hull Iron & Steel Foundries, Ltd.

Drills — Air and Hammer:
Canadian Ingersoll-Rand Co., Ltd
Canadian Rock Drill Co.
Denver Rock Drill Mfg. Co., Ltd.
Herbert, Alfred, Ltd.
Holman Bros., Ltd.
Sullivan Machinery Co.
The Mine & Smelter Supply Co.

Drills — Core:
Canadian Ingersoll-Rand Co., Ltd.
Herbert, Alfred, Limited
Holman Bros., Ltd.
Sullivan Machineery Co.

Drill Steel Furnaces:
Canadian Ingersoll-Rand Co., Ltd.
Denver Rock Drill Mfg. Co.
Herbert, Alfred, Limited
Holman Bros., Ltd.
Sullivan Machinery Co.

Drills — Diamond:
Sullivan Machinery Co.

Drill Steel — Mining:
Canadian Ingersoll-Rand Co., Ltd..
Hadfields, Limited
Mussens, Limited

Drill Steel Sharpeners:
Canadian Ingersoll-Rand Co., Ltd.

Drills — Electric:
Herbert, Alfred, Limited
Holman Bros. Ltd.
Sullivan Machinery Co.
Northern Electric Co., Ltd.

Drills — High Speed and Carbon:
Hadfields, Limited
Herbert, Alfred, Limited
Holman Bros, Ltd.

Ejectors:
Canadian Ingersoll-Rand Co., Ltd.

Electric Condensers:
Griswold & Co.
Canadian Rock Drill Co.
Denver Rock Drill Mfg. Co., Ltd.
Herbert, Alfred, Limited
Holman Bros., Limited
Northern Canada Supply Co.

Electric Hoists:
Canadian Mead-Morrison Co.

Elevators:
Dodge Manufacturing Co.
Canadian Machinery Co.
Sullivan Machinery Co.
Link-Belt Limited.
Northern Canada Supply Co.
Hadfields, Limited.
Jones & Glassco (Regd.).

Engineering & Surveying Instruments:
Laurie & Lamb.

Engines — Ventilating:
Canadian Sirocco Co., Ltd.

Engines, Diesel:
Bellis & Morcom Ltd.
Laurie & Lamb
Lammers & Maase, Ltd.

Engines — Gas and Gasoline:
Belliss & Morcom, Ltd.
Sullivan Machinery Co.
Gould, Shapely & Muir Co., Ltd.
Laurie & Lamb.
The Mine & Smelter Supply Co.
Powley & Moody, Limited.

Engines — Haulage:
Canadian Ingersoll-Rand Co., Ltd.
Powley & Moody, Limited.

Engines — Steam:
Canadian Ingersoll-Rand Co., Ltd.
Laurie & Lamb.

Engineers:
Dresser, John A.
Dorr Co.
Ferrier, W. F.
Hore, R. E.
Heves & Sons, Thos.
Hersey Co. Ltd., Milton
McEvoy, James C.
Rogers, George R.
Ross, Jas. G.
Stewart, Robert H.
